Augmented $\ell_1$ and Nuclear-Norm Models with a Globally Linearly Convergent Algorithm

Ming-Jun Lai† and Wotao Yin‡

Abstract. This paper studies the long-existing idea of adding a nice smooth function to “smooth” a nondifferentiable objective function in the context of sparse optimization, in particular, the minimization of $\|x\|_1 + \frac{1}{2\alpha}\|x\|_2^2$, where $x$ is a vector, as well as the minimization of $\|X\|_* + \frac{1}{2\alpha}\|X\|_F^2$, where $X$ is a matrix and $\|X\|_*$ and $\|X\|_F$ are the nuclear and Frobenius norms of $X$, respectively. We show that they let sparse vectors and low-rank matrices be efficiently recovered. In particular, they enjoy exact and stable recovery guarantees similar to those known for the minimization of $\|x\|_1$ and $\|X\|_*$ under the conditions on the sensing operator such as its null-space property, restricted isometry property (RIP), spherical section property, or “RIPless” property. To recover a (nearly) sparse vector $x^0$, minimizing $\|x\|_1 + \frac{1}{2\alpha}\|x\|_2^2$ returns (nearly) the same solution as minimizing $\|x\|_1$ whenever $\alpha \geq 10\|x^0\|_\infty$. The same relation also holds between minimizing $\|X\|_* + \frac{1}{2\alpha}\|X\|_F^2$ and minimizing $\|X\|_*$ for recovering a (nearly) low-rank matrix $X^0$ if $\alpha \geq 10\|X^0\|_2$. Furthermore, we show that the linearized Bregman algorithm, as well as its two fast variants, for minimizing $\|x\|_1 + \frac{1}{2\alpha}\|x\|_2^2$ subject to $Ax = b$ enjoys global linear convergence as long as a nonzero solution exists, and we give an explicit rate of convergence. The convergence property does not require a sparse solution or any properties on $A$. To the best of our knowledge, this is the best known global convergence result for first-order sparse optimization algorithms.

Key words. sparse optimization, global linear convergence, compressed sensing, low-rank matrix, matrix completion, exact regularization

DOI. 10.1137/120863290

1. Introduction. Sparse vector recovery and low-rank matrix recovery problems have drawn much attention from researchers in different fields over the past several years. They have wide applications in compressive sensing, signal/image processing, machine learning, etc. The fundamental problem of sparse vector recovery is to find the vector with (nearly) fewest nonzero entries from an underdetermined linear system $Ax = b$, and that of low-rank matrix recovery is to find a matrix of (nearly) lowest rank from an underdetermined $A(X) = b$, where $A$ is a linear operator.

To recover a sparse vector $x^0$, a well-known model is the basis pursuit (BP) problem [12]:

$$\min_x \{\|x\|_1 : Ax = b\}. \tag{1}$$
For vector $b$ with noise or generated by an approximately sparse vector, a variant of (1) is

$$\min_x \{ \|x\|_1 : \|Ax - b\|_2 \leq \sigma \}. \tag{2}$$

To recover a low-rank matrix $X^0 \in \mathbb{R}^{n_1 \times n_2}$ from linear measurements $b = A(X^0)$, which stand for $b_i = \text{trace}(A_i^\top X^0)$ for a given matrix $A_i \in \mathbb{R}^{n_1 \times n_2}$, $i = 1, 2, \ldots, m$, a popular approach is the convex model (cf. [15, 9, 37])

$$\min_X \{ \|X\|_* : A(X) = b \}, \tag{3}$$

where $\|X\|_*$ equals the summation of the singular values of $X$. Similar to (2), a useful variant of (3) is

$$\min_X \{ \|X\|_* : \|A(X) - b\|_2 \leq \sigma \}. \tag{4}$$

The nonsmooth objective functions in problems (1)–(4) pose numerical challenges. We augment or “smooth” them by adding $\frac{1}{2\alpha}\|x\|_2^2$ or $\frac{1}{2\alpha}\|X\|_F^2$, where $\alpha$ is a positive scalar. We argue that minimizing the augmented objective $\|x\|_1 + \frac{1}{2\alpha}\|x\|_2^2$, as well as $\|X\|_* + \frac{1}{2\alpha}\|X\|_F^2$, leads to fast numerical algorithms because not only can accurate solutions be obtained by using a sufficiently large, yet not excessively large, value of $\alpha$, but the Lagrange dual problems are also continuously differentiable and subject to gradient-based acceleration techniques such as line search.

Next, we briefly review the related works and summarize the contributions of this paper. The augmented model for (1) is

$$\min_x \left\{ \|x\|_1 + \frac{1}{2\alpha}\|x\|_2^2 : Ax = b \right\}, \tag{5}$$

which can be solved by the linearized Bregman algorithm (LBreg) [41], which is analyzed in [4, 40]. (Note that LBreg is different from the Bregman algorithm [33, 41], which solves problem (1) instead of (5).)

The exact regularization property of (5) is proved in [40]: the solution to (5) is also a solution to (1) as long as $\alpha$ is sufficiently large. The property can also be obtained from [18]. However, neither paper tells one how to select $\alpha$, whereas the size of $\alpha$ affects the numerical performance. It has been observed by several groups of researchers that a larger $\alpha$ tends to cause slower convergence. Hence, one would like to choose a moderate $\alpha$ that is just large enough for (5) to return a solution to (1). For recovering a sparse vector $x^0$ and a low-rank matrix $X^0$, this paper gives the simple formulae

$$\alpha \geq 10\|x^0\|_\infty \quad \text{and} \quad \alpha \geq 10\|X^0\|_2,$$

respectively, where the operator norm $\|X^0\|_2$ equals the maximum singular value of $X^0$. Although $x^0$ and $X^0$ are not known when $\alpha$ must be set, $\|x^0\|_\infty$ and $\|X^0\|_2$ are often easy to estimate. For example, in compressive sensing, $\|x^0\|_\infty$ is the maximum intensity of the underlying signal or the maximum sensor reading. When the total energy $\|x^0\|_2$ is roughly known,
one can apply the more conservative formula $\alpha \geq 10\|x^0\|_2$ since $\|x^0\|_2 \geq \|x^0\|_\infty$. Similarly, a more conservative formula for the matrix case is $\alpha \geq 10\|X^0\|_F$.

This paper also shows that the Lagrange dual problem of (5) is unconstrained and differentiable, and its objective is uniformly strongly convex when restricted to certain pairs of points. Consequently, algorithm LBreg, as well as two faster variants, enjoys global linear convergence; specifically, both the objective error and solution error are bounded by $O(\mu^k)$, where $k$ is the iteration number and $\mu$ is a constant strictly less than 1. The value of $\mu$ depends on $\alpha$, the dynamic range of the solution’s nonzero entries, as well as some properties of $A$. Although several first-order algorithms for (1) have been shown to have asymptotic linear convergence, this is the first global linear convergence result that comes with an explicit rate.

We shall discuss strong convexity. Many of the algorithms for recovering sparse solutions from underdetermined systems of equations are observed to have a linearly converging behavior, at least on problems that are not severely “ill-conditioned”; however, their underlying objective functions do not have strong convexity—a property commonly used to ensure global linear convergence—when the linear operator $A$ has fewer rows than columns. Specifically, the loss function in the form of $g(Ax - b)$, even for strongly convex function $g$, is “flat” along many directions. Flatness or near flatness along a direction means a small directional gradient, which can generally cause a slow decrease in the objective value. However, in problems with certain types of matrix $A$, moving along these directions will significantly change the regularization function. In the recent paper [1], the definition of strong convexity is extended to include a relaxation term involving the regularizer function. The paper argues that, with high probability for problems with $A$ that is random or satisfies restricted eigenvalue or other suitable properties, their “restricted strong convexity” definition is satisfied by the sum of the regularization and loss functions, and, as a result, the prox-linear or gradient projection iteration applied to minimizing the sum has a (nearly) linear convergence behavior, specifically,

$$\|x^{(k+1)} - x^*\|_2^2 \leq c^k \|x^{(0)} - x^*\|_2^2 + o(\|x^* - x^0\|_2^2),$$

where $c < 1$, $x^*$ and $x^0$ are the minimizer and underlying true signal, respectively, and $x^{(k)}$ stands for the $k$th iterate. This paper presents a different approach. Due to smoothing, unmodified linear convergence to the exact solution is achievable without a probabilistic argument. The Lagrange dual of (5) is strongly convex, not in the global sense, but restricted between the current point and its projection to the solution set. This property turns out to be sufficient for global linear convergence without a modification.

Numerically, LBreg without acceleration is not very efficient because it is equivalent to the dual gradient ascent with a fixed step size, as shown in [40]. Nonetheless, the step size can be relaxed. Since the augmentation term $\frac{1}{2\alpha^2}\|x\|_2^2$ makes the dual problem unconstrained and differentiable, the dual is subject to advanced gradient-descent techniques such as Barzilai–Borwein (BB) step sizes [2], nonmonotone line search, and Nesterov’s technique [31], as well as semismooth Newton methods. Indeed, LBreg has been improved in several recent works: [34] applies a kicking trick; [40] considers applying BB step sizes and nonmonotone line search, as well as the limited memory BFGS method [28]; [39] applies the alternating direction method to the Lagrange dual of (5); and [24] applies Nesterov’s technique [31] and obtains the convergence rate $O(1/k^2)$. Based on the restricted strong convexity of the dual objective and some
existing proofs, we theoretically show and numerically demonstrate that LBreg with BB step
sizes with nonmonotone line search also enjoys global linear convergence.

LBreg has also been extended to recovering simply structured matrices. The algorithms
type; namely, they are gradient iterations that solve
\[
\min_X \left\{ \|X\|_* + \frac{1}{2\alpha} \|X\|_F^2 : X_{ij} = M_{ij} \forall (i, j) \in \Omega \right\},
\]
\[
\min_{L, S} \left\{ \|L\|_* + \lambda \|S\|_1 + \frac{1}{2\alpha} (\|L\|_F^2 + \|S\|_F^2) : L + S = D \right\},
\]
respectively, where \(\Omega\) is the set of the observed matrix entries and \(\|S\|_1 = \sum_{i,j} |S_{ij}|\). The
paper [42] shows that the exact regularization property for the vector case also holds for
(6) and (7). Although this paper does not analyze (6) and (7) specifically, it gives recovery
guarantees for models
\[
\min_X \left\{ \|X\|_* + \frac{1}{2\alpha} \|X\|_F^2 : A(X) = b \right\}
\]
and
\[
\min_X \left\{ \|X\|_* + \frac{1}{2\alpha} \|X\|_F^2 : \|A(X) - b\|_2 \leq \sigma \right\}
\]
assuming \(\alpha \geq 10 \|X^0\|_2\).

1.1. Organization. The rest of this paper is organized as follows. Section 2 presents
several models with augmented \(\ell_1\) or augmented nuclear-norm objectives and derives their
Lagrange dual problems. The exact and stable recovery conditions for these models are given
in section 3. Section 4 proves a restricted strongly convex property and establishes global
linear convergence for LBreg and its two faster variants. The materials of sections 3 and 4 are
technically independent of each other, yet they are two important sides of model (5).

The MATLAB codes and demos of LBreg, including the original, line search, and Nesterov
acceleration versions, can be found on the second author’s homepage (http://www.wotaoyin.
com).

2. Augmented \(\ell_1\) and nuclear-norm models. This section presents the primal and dual
problems of a few augmented \(\ell_1\) and augmented nuclear-norm models.

Equality constrained augmented \(\ell_1\) model. Since \(\|x\|_1 = \max\{x^\top z : z \in \mathbb{R}^n, \|z\|_\infty \leq 1\}\),
the dual problem of (5) can be obtained as follows:
\[
\min_x \left\{ \|x\|_1 + \frac{1}{2\alpha} \|x\|_2^2 : Ax = b \right\} = \min_x \max_y \left\{ \|x\|_1 + \frac{1}{2\alpha} \|x\|_2^2 - y^\top (Ax - b) \right\}
= \min_x x^\top z + \frac{1}{2\alpha} \|x\|_2^2 - y^\top Ax + y^\top b : \|z\|_\infty \leq 1
= \max_y \min_x x^\top z + \frac{1}{2\alpha} \|x\|_2^2 - y^\top Ax + b^\top y : \|z\|_\infty \leq 1
= -\min_y \left\{ -b^\top y + \frac{\alpha}{2} \|A^\top y - z\|_2^2 : \|z\|_\infty \leq 1 \right\}
\]
since \(x^* = \alpha (A^\top y - z)\).
Eliminating \(z\) from the last equation gives the following dual problem:

\[
\begin{align*}
\text{(10)} \quad & \min_{y} -b^\top y + \frac{\alpha}{2} \|A^\top y - \text{Proj}_{[-1,1]}(A^\top y)\|_2^2. \\
\end{align*}
\]

For any real vector \(z\), we have \(z - \text{Proj}_{[-\mu,\mu]}(z) = \text{shrink}_\mu(z)\), where \(\text{shrink}_\mu\) is the well-known shrinkage or soft-thresholding operator with parameter \(\mu > 0\). We omit \(\mu\) when \(\mu = 1\). Hence, the second term in (10) equals \((\alpha/2)\|\text{shrink}(A^\top y)\|_2^2\).

It is interesting to compare (10) with the Lagrange dual of (1):

\[
\begin{align*}
\text{(11)} \quad & \min_y \{- b^\top y : \|A^\top y\|_\infty \leq 1\}. \\
\end{align*}
\]

Instead of confining each component of \(A^\top y\) to \([-1, 1]\), (10) applies a quadratic penalty to the violation. This leads to its advantage of being unconstrained and differentiable (despite the presence of projection).

The gradient of the last term in (10) is \(\alpha A \text{shrink}(A^\top y)\). Furthermore, given a solution \(y^*\) to (10), one can recover the solution \(x^* = \alpha \text{shrink}(A^\top y^*)\) to (5) (since (10) has a vanishing gradient \(Ax^* - b = 0\), and \(x^*\) and \(y^*\) lead to 0-gap primal and dual objectives, respectively). Therefore, solving (10) solves (5), and it is easier than solving (1). In particular, (10) enjoys a rich set of classical techniques such as line search, BB steps [2], semismooth Newton methods, and Nesterov’s acceleration [31], which do not directly apply to problem (1) or (11).

**Norm-constrained augmented \(\ell_1\).** For model (2), the primal and dual augmented models are

\[
\begin{align*}
\text{(12)} \quad & \min_x \left\{ \|x\|_1 + \frac{1}{2\alpha} \|x\|_2^2 : \|Ax - b\|_2 \leq \sigma \right\}, \\
\text{(13)} \quad & \min_y \left\{ -b^\top y + \sigma \|y\|_2 + \frac{\alpha}{2} \|A^\top y - \text{Proj}_{[-1,1]}(A^\top y)\|_2^2 \right\}. \\
\end{align*}
\]

The objective of (13) is differentiable except at \(y = 0\). However, this is not an issue since \(y = 0\) is a solution to (13) only if \(x = 0\) is the solution to (12). In other words, (13) is practically differentiable and thus also amenable to classical gradient-based acceleration techniques.

**Equality-constrained augmented \(\|\cdot\|_*\).** The primal and dual of the augmented model of (3) are (8) and

\[
\begin{align*}
\text{(14)} \quad & \min_y \left\{ -b^\top y + \frac{\alpha}{2} \|A^*y - \text{Proj}_{\{X:\|X\|_2 \leq 1\}}(A^*y)\|_F^2 \right\}, \\
\end{align*}
\]

respectively, where \(A^*y := \sum_{i=1}^n y_i A_i\) and \(\{X : \|X\|_2 \leq 1\}\) is the set of \(n_1\)-by-\(n_2\) matrices with spectral norms no more than 1. In (14), inside the Frobenius norm is the singular value soft-thresholding [3] of \(A^*y\).

The primal and dual of the augmented model (4) are (9) and

\[
\begin{align*}
\text{(15)} \quad & \min_y \left\{ -b^\top y + \sigma \|y\|_2 + \frac{\alpha}{2} \|A^*y - \text{Proj}_{\{X:\|X\|_2 \leq 1\}}(A^*y)\|_2^2 \right\}, \\
\end{align*}
\]

respectively. Like the augmented models for vectors, problems (14) and (15) are practically differentiable and thus also amenable to advanced optimization techniques for unconstrained differentiable problems.
As one can see, it is a routine task to augment an $\ell_1$-like minimization problem and obtain a problem with a strongly convex objective, as well as its Lagrange dual with a differentiable objective and no constraints. One can augment models with a transform-$\ell_1$ objective, total variation, $\ell_1$, $\ell_2$, or $\ell_1,\infty$ norms (for joint or group sparse signal recovery), robust-PCA objective, etc. Since the dual problems are convex and differentiable, they enjoy a rich set of gradient-based optimization techniques.

3. Recovery guarantees. This section establishes recovery guarantees for augmented $\ell_1$ models (5) and (12) and extends these results to matrix recovery models (8) and (9). The results for (5) and (12) are given based on a variety of properties of $A$ including the null-space property (NSP) in Theorem 3.1, the restricted isometry property (RIP) \cite{10} in Theorems 3.3 and 3.5, the spherical section property (SSP) \cite{45} in Theorems 3.7 and 3.8, and an “RIPless” condition \cite{7} in Theorem 3.9. We choose to study all these different properties since they give different types of recovery guarantees and apply to different types of matrices. Other than the fact that NSP is used in our proofs for RIP and SSP, the other three properties—RIP, SSP, and RIPless—do not dominate one another in terms of usefulness. Together they assert that a large number of matrices, such as those sampled from sub-Gaussian distributions, Fourier and Wash–Hadamard ensembles, and random Toeplitz and circulant ensembles, are suitable for sparse vector recovery by models (5) and (12).

First, we present some numerical simulations to motivate the subsequent analysis.

3.1. Motivating examples. We are interested in comparing model (5) to model (1), whose performance on recovering sparse solutions has been widely studied. To this end, we conducted three sets of simulations. Without loss of generality, we fixed $\|x_0\|\infty = 1$ and solved (1) and then (5) with $\alpha = 1, 10, \text{ and } 25$ to reconstruct signals of $n = 400$ dimensions. We set the signal sparsity $k = 1, 2, \ldots, 80$ and the number of measurements $m = 40, 41, \ldots, 200$. The entries of $A$ were sampled from the standard Gaussian distribution.

It turns out that the recovery performance of (5) depends on the decay speed of the nonzero entries of the signal $x_0$. So, we tested three decay speeds: (i) flat magnitude—no decay, (ii) independent Gaussian—moderate decay, and (iii) power-law—fast decay. In the power-law decay, the $i$th largest entry had magnitude $i^{-2}$ and a random sign.

For each $(m, k)$, 100 independent tests were run, and the average of

$$
\text{recovery relative error } \|x^* - x_0\|_2/\|x_0\|_2
$$

was recorded, where $x^*$ stands for a solution of either (1) or (5). The slightly smoothed cut-off curves at two different levels of relative errors are depicted in Figure 1. Above each curve is the region where a model fails to recover the signals to the specified average relative error. Hence, a higher curve means fewer fails and thus better recovery performance.

We can make the following observations.

- In all tests, the best curve is from BP, or model (1). Closely following it are those of $\alpha = 25$ and $\alpha = 10$ of model (5). As long as $\alpha \geq 10$, model (5) is as good as model (1) up to a negligible difference.
- The curve of $\alpha = 1$ is noticeably lower than the others when the signal is flat or decays slowly. For this reason, we do not recommend using $\alpha = \|x_0\|\infty$ for model (5) except when the underlying signals decay very fast.
The differences of the four curves are very similar across the two levels $10^{-3}$ and $10^{-5}$ of relative errors. We tested other levels and found the same. Therefore, the performance differences are independent of the error level chosen to plot the curves.

Some expert readers may know that, in theory, given matrix $A$, whether or not model (1) can exactly recover $x^0$ depends solely on $\text{sign}(x^0)$, independent of its decay speed. So, one may wonder why the BP curves are not the same across different plots. That is because, when (1) fails to recover $x^0$, the relative error depends on the decay speed; a faster decaying signal, when not exactly recovered, tends to have a smaller error. This is why at the error level $10^{-3}$, the BP curve is obviously higher (better) on the faster-decaying signals.

### 3.2. Null-space property

Matrix $A$ satisfies the NSP if

\begin{equation}
\|h_S\|_1 < \|h_{S^c}\|_1
\end{equation}

holds for all $h \in \text{Null}(A)$ and coordinate sets $S \subset \{1, 2, \ldots, n\}$ of cardinality $|S| \leq k$. If so, problem (1) recovers all $k$-sparse vectors $x^0$ from measurements $b = Ax^0$. The NSP is also necessary for exact recovery of all $k$-sparse vectors uniformly. The wide use of the NSP can be found in, e.g., [13, 20, 44]. Note that it holds regardless of the value of $\|x^0\|_\infty$. We now give a necessary and sufficient condition for problem (5).
Theorem 3.1 (NSP condition). Assume that \( \|x^0\|_\infty \) is fixed. Problem (5) uniquely recovers all \( k \)-sparse vectors \( x^0 \) with the fixed \( \|x^0\|_\infty \) from measurements \( b = Ax^0 \) if and only if

\[
(1 + \frac{\|x^0\|_\infty}{\alpha}) \|h_S\|_1 \leq \|h_S\|_1
\]

holds for all vectors \( h \in \text{Null}(A) \) and coordinate sets \( S \) of cardinality \( |S| \leq k \).

Proof. Sufficiency: Pick any \( k \)-sparse vector \( x^0 \). Let \( S := \text{supp}(x^0) \) and \( Z = S^c \). For any nonzero \( h \in \text{Null}(A) \), we have \( A(x^0 + h) = Ax^0 = b \) and

\[
\|x^0 + h\|_1 + \frac{1}{2\alpha}\|x^0 + h\|_2^2 \\
= \|x^0_S + h_S\|_1 + \frac{1}{2\alpha}\|x^0_S + h_S\|_2^2 + \|h_Z\|_1 + \frac{1}{2\alpha}\|h_Z\|_2^2 \\
\geq \|x^0_S\|_1 - \|h_S\|_1 + \frac{1}{2\alpha}\|x^0_S\|_2^2 + \|h_Z\|_1 + \frac{1}{2\alpha}\|h_Z\|_2^2 \\
\geq \left[ \|x^0_S\|_1 + \frac{1}{2\alpha}\|x^0_S\|_2^2 \right] + \left[ \|h_Z\|_1 - \|h_S\|_1 - \frac{\|x^0_S\|_\infty}{\alpha} \|h_S\|_1 \right] + \frac{1}{2\alpha}\|h\|_2^2
\]

for any \( h \in \text{Null}(A) \) and coordinate sets \( S \) of cardinality \( |S| \leq k \). Since \( \|h\|_2^2 > 0 \), \( \|x^0 + h\|_1 + \frac{1}{2\alpha}\|x^0 + h\|_2^2 \) is strictly larger than \( \|x^0\|_1 + \frac{1}{2\alpha}\|x^0\|_2^2 \). Let \( \tau \) be the unique minimizer of (19).

Necessity: It is sufficient to show that for any given nonzero \( h \in \text{Null}(A) \) and \( S \) satisfying \( |S| \leq k \), we can identify a \( k \)-sparse \( x^0 \) such that (18) is necessary for its exact recovery. To this end, we define \( x^0 \) as \( x^0_i = -\text{sign}(h_i)\|h\|_\infty \) for \( i \in S \) and \( x^0_j = 0 \) for \( j \in S^c \), and scale \( x^0 \) to have the specified \( \|x^0\|_\infty \). Under this construction, we have the following properties:

\[
\|x^0\|_\infty \leq k, \quad \|x^0_S + \tau h_S\|_1 = \|x^0_S\|_1 - \|\tau h_S\|_1, \quad \langle x^0_S, \tau h_S \rangle = -\|x^0_S\|_\infty \|h_S\|_1
\]

for any \( 0 < \tau \leq 1 \). Now, we let \( \tau h \) replace \( h \) in the equation array (19) and observe that both of the inequalities of (19) hold with equality. Therefore, since the exact recovery of \( x^0 \) requires \( \|x^0 + \tau h\|_1 + \frac{1}{2\alpha}\|x^0 + \tau h\|_2^2 > \|x^0\|_1 + \frac{1}{2\alpha}\|x^0\|_2^2 \), it also requires

\[
(20) \quad \left[ \|\tau h_Z\|_1 - \left( 1 + \frac{\|x^0\|_\infty}{\alpha} \right) \|\tau h_S\|_1 \right] + \frac{1}{2\alpha}\|\tau h\|_2^2 > 0
\]

for all \( 0 < \tau \leq 1 \), which in turn requires (18) to hold.

Remark 1. For any finite \( \alpha > 0 \), (18) is stronger than (17) due to the extra term \( \|x^0_S\|_\infty \). Since various uniform recovery results establish conditions that guarantee (17), one can tighten these conditions so that they guarantee (18) and thus the uniform recovery by problem (5). How much tighter these conditions have to be depends on the value \( \frac{\|x^0_S\|_\infty}{\alpha} \).
3.3. Restricted isometry property. In this subsection, we first review the RIP-based sparse recovery guarantees and then show that, given certain RIP conditions, any $\alpha \geq 10\|x^0\|_\infty$ guarantees exact and stable recovery by (5) and (12), respectively.

Definition 3.2 (see [10]). The RIP constant $\delta_k$ of matrix $A$ is the smallest value such that

\begin{equation}
(1 - \delta_k)\|x\|_2^2 \leq \|Ax\|_2^2 \leq (1 + \delta_k)\|x\|_2^2
\end{equation}

holds for all $k$-sparse vectors $x \in \mathbb{R}^n$.

For (1) to recover any $k$-sparse vector uniformly, [6] shows the sufficiency of $\delta_{2k} < 0.4142$, which is later improved to $\delta_{2k} < 0.4531$ [17], $\delta_{2k} < 0.4652$ [16], $\delta_{2k} < 0.4721$ [5], as well as $\delta_{2k} < 0.4931$ [29]. The bound is still being improved. Adapting results in [29], we give the uniform recovery conditions for (5) below.

Theorem 3.3 (RIP condition for exact recovery). Assume that $x^0 \in \mathbb{R}^n$ is $k$-sparse. If $A$ satisfies RIP with $\delta_{2k} \leq 0.4404$ and $\alpha \geq 10\|x^0\|_\infty$, then $x^0$ is the unique minimizer of (5) given measurements $b := Ax^0$.

Proof. Let $S := \text{supp}(x^0)$ and $Z := S^c$. Theorem 3.1 in [29] shows that any $h \in \text{Null}(A)$ satisfies

\[ \|h_S\|_1 \leq \theta_{2k}\|h_Z\|_1, \]

where

\begin{equation}
\theta_{2k} := \sqrt{\frac{4(1 + 5\delta_{2k} - 4\delta_{2k}^2)}{(1 - \delta_{2k})(32 - 25\delta_{2k})}}.
\end{equation}

Hence, (18) holds, provided that

\[ \left(1 + \frac{\|x^0\|_\infty}{\alpha}\right)^{-1} \geq \theta_{2k} \]

or, in light of $\theta_{2k} < 1$,

\begin{equation}
\alpha \geq \left(\theta_{2k}^{-1} - 1\right)^{-1}\|x^0\|_\infty = \frac{\|x^0\|_\infty \cdot \sqrt{4(1 + 5\delta_{2k} - 4\delta_{2k}^2)}}{\sqrt{(1 - \delta_{2k})(32 - 25\delta_{2k})} - \sqrt{4(1 + 5\delta_{2k} - 4\delta_{2k}^2)}}.
\end{equation}

For $\delta_{2k} = 0.4404$, we obtain $(\theta_{2k}^{-1} - 1)^{-1}\|x^0\|_\infty \approx 9.9849\|x^0\|_\infty \leq \alpha$, which proves the theorem.

Remark 2. Different values of $\delta_{2k}$ are associated with different conditions on $\alpha$. Following (23), if $\delta_{2k} \leq 0.4715$, $\alpha \geq 25\|x^0\|_\infty$ guarantees exact recovery. If $\delta_{2k} \leq 0.1273$, $\alpha \geq \|x^0\|_\infty$ guarantees exact recovery. In general, a smaller $\delta_{2k}$ allows a smaller $\alpha$.

Next we study the case where $b$ is noisy or $x^0$ is not exactly sparse, or both. For comparison, we present two inequalities next to each other for each of problems (2) and (5), where the first one is easy to obtain; see [6] for an example.

Lemma 3.4. Let $x^0 \in \mathbb{R}^n$ be an arbitrary vector, $S$ be the coordinate set of its $k$ largest components in magnitude, and $Z := \{1, \ldots, n\} \setminus S$. Let $x^*$ and $x^*$ be the solutions of (2) and
Also, \( \| x^0 \|_1 \geq \| x^0 \|_2 \) and \( h = x^* - x^0 \) satisfy

\[
\begin{align*}
\| h \|_1 & \leq \| h \|_1 + 2 \| x^0 \|_1, \\
\| h \|_1 & \leq C_3 \| h \|_1 + C_4 \| x^0 \|_1,
\end{align*}
\]

where \( \| x^0 \|_1 \) is the best k-term approximation error of \( x^0 \) and

\[
C_3 := \frac{\alpha + \| x^0 \|_\infty}{\alpha - \| x^0 \|_\infty} \quad \text{and} \quad C_4 := \frac{2 \alpha}{\alpha - \| x^0 \|_\infty}.
\]

**Proof.** We show only (25). Since \( x^* = x^0 + h \) is the minimizer of (12), we have

\[
\| x^0 + h \|_1 + \frac{1}{2\alpha} \| x^0 + h \|_2^2 \leq \| x^0 \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2.
\]

Also,

\[
\begin{align*}
\| x^0 + h \|_1 + \frac{1}{2\alpha} \| x^0 + h \|_2^2 & = \| x^0 \|_1 + \| h \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2 + \| h \|_2 + \| h \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2 \\
& \geq \frac{\alpha + \| x^0 \|_\infty}{\alpha - \| x^0 \|_\infty} \| h \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2 - \frac{1}{\alpha} \langle x^0, h \rangle + \frac{1}{2\alpha} \| h \|_2^2 \\
& \quad + \| h \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2 - \frac{1}{\alpha} \langle x^0, h \rangle + \frac{1}{2\alpha} \| h \|_2^2 \\
& = \left( \| x^0 \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2 \right) - 2 \| x^0 \|_1 - \left( \| h \|_1 + \frac{1}{\alpha} \langle x^0, h \rangle \right) \\
& \quad + \left( \| h \|_1 - \frac{1}{\alpha} \langle x^0, h \rangle \right) + \frac{1}{2\alpha} \| h \|_2^2 \\
& \geq \left( \| x^0 \|_1 + \frac{1}{2\alpha} \| x^0 \|_2^2 \right) - 2 \| x^0 \|_1 - \left( 1 + \frac{\| x^0 \|_\infty}{\alpha} \right) \| h \|_1 \\
& \quad + \left( 1 - \frac{\| x^0 \|_\infty}{\alpha} \right) \| h \|_1 + \frac{1}{2\alpha} \| h \|_2^2,
\end{align*}
\]

where the first inequality follows from the triangle inequality, and the second from \( \langle a, b \rangle \leq \| a \|_\infty \| b \|_1 \). Combining (27) and (28), we obtain

\[
\left( 1 - \frac{\| x^0 \|_\infty}{\alpha} \right) \| h \|_1 + \frac{1}{2\alpha} \| h \|_2^2 \leq \left( 1 + \frac{\| x^0 \|_\infty}{\alpha} \right) \| h \|_1 + 2 \| x^0 \|_1
\]

and thus (25) after dropping the nonnegative term \( \frac{1}{2\alpha} \| h \|_2^2 \). \( \square \)

We now present the stable recovery guarantee.

**Theorem 3.5 (RIP condition for stable recovery).** Assume the setting of Lemma 3.4. Let \( b := Ax^0 + n \), where \( n \) is an arbitrary noisy vector with \( \| n \|_2 \leq \sigma \). If \( A \) satisfies RIP with \( \delta_{2k} \leq 0.3814 \), then the solution \( x^* \) of (12) with any \( \alpha \geq 10 \| x^0 \|_\infty \) satisfies

\[
\begin{align*}
\| x^* - x^0 \|_1 & \leq C_1 \cdot \sqrt{k} \| n \|_2 + C_2 \cdot \| x^0 \|_1, \\
\| x^* - x^0 \|_2 & \leq \tilde{C}_1 \cdot \| n \|_2 + \tilde{C}_2 \cdot \| x^0 \|_1 / \sqrt{k},
\end{align*}
\]
where $C_1$, $C_2$, $\tilde{C}_1$, and $\tilde{C}_2$ are given in (33a)-(34b) as functions of only $\delta_{2k}$, $C_3$, and $C_4$ in (26).

Proof. We follow an argument similar to that in [29]. According to Lemma 4.3 of [29], from $\|Ah\|_2 = \|Ax^* - Ax^0\|_2 = \|Ax^* - b + n\|_2 \leq \|Ax^* - b\|_2 + \|n\|_2 \leq 2\|n\|_2$ and $\delta_{2k} < 2/3$, we obtain

$$\|h_S\|_1 \leq \frac{2\sqrt{2}}{\sqrt{1 - \delta_{2k}}} |\mathbf{k}| \|n\|_2 + \theta_{2k} \|h_Z\|_1,$$

where $\theta_{2k}$ is defined in (22) as a function of $\delta_{2k}$. It is easy to verify that with the choice of $\delta_{2k} \leq 0.3814$ and $\alpha$ in the theorem, $C_3\theta_{2k} < 1$ holds for all nonzero $x^0$. Hence, combining (25) of Lemma 3.4 and (31) yields the bound of $\|h_Z\|_1$:

$$\|h_Z\|_1 \leq (1 - C_3\theta_{2k})^{-1} \left( C_3 \frac{2\sqrt{2}}{\sqrt{1 - \delta_{2k}}} |\mathbf{k}| \|n\|_2 + C_4 \|x^0\|_1 \right).$$

Applying (31) and (32) gives us (29) or

$$\|x^* - x^0\|_1 = \|h\|_1 = \|h_S\|_1 + \|h_Z\|_1 \leq \frac{2\sqrt{2}}{\sqrt{1 - \delta_{2k}}} \sqrt{|\mathbf{k}|} \|n\|_2 + (1 + \theta_{2k}) \|h_Z\|_1 \leq C_1 \sqrt{|\mathbf{k}|} \|n\|_2 + C_2 \|x^0 - \sigma_k(x^0)\|_1,$$

where

$$C_1 = \frac{2\sqrt{2}(1 + C_3)}{\sqrt{1 - \delta_{2k}}(1 - C_3\theta_{2k})},$$

$$C_2 = \frac{(1 + \theta_{2k})C_4}{1 - C_3\theta_{2k}}.$$  

To prove (30), we apply (32) to the inequality (page 7 of [29])

$$\|h\|_2 \leq \frac{2}{\sqrt{1 - \delta_{2k}}} \|n\|_2 + \sqrt{\frac{8(2 - \delta_{2k})}{(1 - \delta_{2k})(32 - 25\delta_{2k})}} \|h_Z\|_1 \sqrt{|\mathbf{k}|},$$

and obtain (30) or

$$\|x^* - x^0\|_2 = \|h\|_2 \leq \tilde{C}_1 \|n\|_2 + \tilde{C}_2 \|x^0 - x^0_{|k}\|_1 / \sqrt{|\mathbf{k}|},$$

where

$$\tilde{C}_1 := \frac{2}{\sqrt{1 - \delta_{2k}}} \left( \frac{4C_3}{1 - C_3\theta_{2k}} \sqrt{\frac{2 - \delta_{2k}}{(1 - \delta_{2k})(32 - 25\delta_{2k})}} + 1 \right),$$

$$\tilde{C}_2 := \frac{2C_4}{1 - C_3\theta_{2k}} \sqrt{\frac{2(2 - \delta_{2k})}{(1 - \delta_{2k})(32 - 25\delta_{2k})}}.$$  

Remark 3. A key inequality in the proof above is $C_3 \theta_{2k} < 1$, where $C_3$ (cf. (26)) depends on $\alpha$, $\|x^0_S\|_\infty$, and $\|x^0_2\|_\infty$, and $\theta_{2k}$ (cf. (22)) depends on $\delta_{2k}$. If the nonzeros of $x^0$ decay faster in magnitude, $C_3$ becomes smaller, and thus the condition $C_3 \theta_{2k} < 1$ is easier to hold. Therefore, a faster decaying $x^0$ is easier to recover. This is consistent with the numerical simulation in subsection 3.1. In Theorem 3.5, the condition on $\delta_{2k}$ and bound on $\alpha$ are given for the worst case corresponding to no decay, namely, $\|x^0_S\|_\infty = \|x^0_2\|_\infty$. If $\|x^0_S\|_\infty > \|x^0_2\|_\infty$, one can allow a larger $\delta_{2k}$ for each fixed $\alpha$ or, equivalently, a smaller $\alpha$ for each fixed $\delta_{2k}$. For example, if $\|x^0_S\|_\infty \geq 10\|x^0_2\|_\infty$, one needs only $\delta_{2k} \leq 0.4348$ instead of the theorem-assumed condition $\delta_{2k} \leq 0.3814$.

There is also a trade-off between $\delta_{2k}$ and $\alpha$. Under the worst case $\|x^0_S\|_\infty = \|x^0_2\|_\infty$, imposing $\alpha \geq 25\|x^0\|_\infty$ leads to the relaxed condition $\delta_{2k} \leq 0.4489$.

3.4. Spherical section property. Next, we derive exact and stable recovery conditions based on the SSP [45, 38] of $A$, which has the advantage of invariance to left-multiplying nonsingular matrices to the sensing matrix $A$, as pointed out in [45]. On the other hand, more matrices are known to satisfy the RIP than the SSP.

Definition 3.6 ($\Delta$-SSP [38]). Let $m$ and $n$ be two integers such that $m > 0$, $n > 0$, and $m < n$. An $(n - m)$-dimensional subspace $V \subset \mathbb{R}^n$ has the $\Delta$ spherical section property if

$$\tag{35} \frac{\|h\|_1}{\|h\|_2} \geq \sqrt{\frac{m}{\Delta}}$$

holds for all nonzero $h \in V$.

To see the significance of (35), we note that (i) $\frac{\|h\|_1}{\|h\|_2} \geq 2\sqrt{k}$ for all $h \in \text{null}(A)$ is a sufficient condition for the NSP inequality (17), and (ii) due to [26, 19], a uniformly random $(n - m)$-dimensional subspace $V \subset \mathbb{R}^n$ has the SSP for

$$\Delta = C_0(\log(n/m) + 1)$$

with probability at least $1 - \exp(C_1(n - m))$, where $C_0$ and $C_1$ are universal constants. Hence, $m \geq 4k\Delta$ guarantees (17) to hold, and, furthermore, if $\text{null}(A)$ is uniformly random, $m = O(k \log(n/m))$ is sufficient for (17) to hold with overwhelming probability [45, 38]. These results can be extended to the augmented model (5).

Theorem 3.7 (SSP condition for exact recovery). Suppose $\text{null}(A)$ satisfies the $\Delta$-SSP. Let us fix $\|x^0\|_\infty$ and $\alpha > 0$. If

$$\tag{36} m \geq \left(2 + \frac{\|x^0\|_\infty}{\alpha}\right)^2 k\Delta,$$

then the null-space condition (18) holds for all this $h \in \text{null}(A)$ and coordinate sets $S$ of cardinality $|S| \leq k$. By Theorem 3.1, (36) guarantees that problem (5) recovers any $k$-sparse $x^0$ from measurements $b = Ax^0$.

Proof. Let $S$ be a coordinate set with $|S| \leq k$. Condition (18) is equivalent to

$$\tag{37} \left(2 + \frac{\|x^0_S\|_\infty}{\alpha}\right) \|h_S\|_1 \leq \|h\|_1.$$
Since \(|h_S|_1 \leq \sqrt{k}||h_S||_2 \leq \sqrt{k}||h||_2\), (37) holds, provided that
\[
\left(2+\frac{||x^0||_{\infty}}{\alpha}\right)\sqrt{k} \leq ||h||_1 ||h||_2,
\]
which itself holds, in light of (35), provided that (36) holds. ■

Now we consider the case \(Ax^0 = b\), where \(x^0\) is an approximately sparse vector.

**Theorem 3.8 (SSP condition for stable recovery).** Suppose \(\text{Null}(A)\) satisfies the \(\Delta\)-SSP. Let \(x^0 \in \mathbb{R}^n\) be an arbitrary vector, \(S\) be the coordinate set of its \(k\) largest components in magnitude, and \(Z := \{1, \ldots, n\} \setminus S\). Let \(\alpha > 0\) in problem (5). Let \(C_3\) and \(C_4\) be defined in (26).

If
\[
m \geq 4(1+C_3)^2k\Delta,
\]
then the solution \(x^*\) of (5) satisfies
\[
||x^*-x^0||_1 \leq 4C_4||x^0_Z||_1,
\]
where \(||x^0_Z||_1\) is the best \(k\)-term approximation error of \(x^0\).

**Proof.** Let \(h = x^* - x^0 \in \text{Null}(A)\). Let
\[
\tilde{C} = \frac{||h||_1}{||x^0_Z||_1}.
\]
Then (40) is equivalent to
\[
\tilde{C} \leq 4C_4.
\]
Adding \(||h_S||_1\) to (25) and plugging in (41) gives us
\[
||h||_1 \leq (1+C_3)||h_S||_1 + 2C_4\tilde{C}^{-1}||h||_1,
\]
or \((1-2C_4\tilde{C}^{-1})||h||_1 \leq (1+C_3)||h_S||_1\). If \(\tilde{C} \leq 2C_4\), (42) naturally holds. Otherwise, we have \(\tilde{C} > 2C_4\) and
\[
||h||_1 \leq \frac{1+C_3}{1-2C_4\tilde{C}^{-1}}||h_S||_1 \leq \frac{(1+C_3)\sqrt{k}}{1-2C_4\tilde{C}^{-1}}||h||_2.
\]
Now, combining \(\Delta\)-SSP and (39), we obtain
\[
\frac{||h||_1}{||h||_2} \geq \sqrt{\frac{m}{\Delta}} \geq 2(1+C_3)\sqrt{k},
\]
which together with (44) gives (42). ■
3.5. "RIPless" analysis. The “RIPless” analysis [7] gives nonuniform recovery guarantees for a wide class of compressive sensing matrices such as those with independent and identically distributed (i.i.d.) sub-Gaussian entries, orthogonal transform ensembles satisfying an incoherence condition, and random Toeplitz/circulant ensembles, as well as certain tight and continuous frame ensembles, at $O(k \log(n))$ measurements. This analysis is especially useful in situations where the RIP, as well as NSP and SSP, is difficult to check or does not hold. In this subsection, we describe how to adapt the “RIPless” analysis to model (5).

Theorem 3.9 (RIPless for exact recovery). Let $x^0 \in \mathbb{R}^n$ be a fixed $k$-sparse vector. With probability at least $1 - 5/n - e^{-\beta}$, $x^0$ is the unique solution to problem (5) with $b = Ax^0$ and $\alpha \geq 8\|x^0\|_2$ as long as the number of measurements

$$m \geq C_0(1 + \beta)\mu(A) \cdot k \log n,$$

where $C_0$ is a universal constant and $\mu(A)$ is the incoherence parameter of $A$ (see [7] for the definition of $\mu(A)$ and values for various kinds of compressive sensing matrices).

Proof. The proof is mostly the same as that of Theorem 1.1 of [7] except that we shall adapt Lemma 3.2 of [7] to Lemma 3.10 for our model (5). We describe the proof of the theorem very briefly here. For any matrix $A$ satisfying property (46) in Lemma 3.10, the golfing scheme [21] can be used to construct a dual vector $y$ such that $A^*y$ satisfies property (47) in Lemma 3.10. The properties (46) and (47) and the construction are exactly the same as in [7]. Then Lemma 3.10 lets this $A^*y$ guarantee the optimality of $x^0$ to (12). □

Lemma 3.10 (dual certificate). Let $x^0$ be given in Theorem 3.9, and let $S := \text{supp}(x^0)$. If $A = [a_1 \ a_2 \cdots \ a_n]$ satisfies

$$\|(A_S^*A_S)^{-1}\|_2 \leq 2 \text{ and } \max_{i \in S^c}\|A_S^*a_i\|_2 \leq 1$$

and there exists $y$ such that $v = A^*y$ satisfies

$$\|v_S - \text{sign}(x^0_S)\|_2 \leq 1/4 \text{ and } \|v_S\|_\infty \leq 1/4,$$

then $x^0$ is the unique solution to (5) with $b = Ax^0$ and $\alpha \geq 8\|x^0\|_2$.

Proof. Let $Z := S^c$. For any nonzero $h \in \text{Null}(A)$, we have $Ah = 0$ and

$$\|x^0 + h\|_1 + \frac{1}{2\alpha}\|x^0 + h\|_2^2$$

$$= \|x^0_S + h_S\|_1 + \frac{1}{2\alpha}\|x^0_S + h_S\|_2^2 + \|h_Z\|_1 + \frac{1}{2\alpha}\|h_Z\|_2^2$$

$$\geq \|x^0_S\|_1 + \langle \text{sign}(x^0_S), h_S \rangle + \frac{1}{2\alpha}\|x^0_S\|_2^2 + \frac{1}{\alpha}\langle x^0_S, h_S \rangle + \frac{1}{2\alpha}\|h_S\|_2^2 + \|h_Z\|_1 + \frac{1}{2\alpha}\|h_Z\|_2^2$$

$$\geq \left[\|x^0_S\|_1 + \frac{1}{2\alpha}\|x^0_S\|_2^2\right] + \left[\langle \text{sign}(x^0_S), h_S \rangle + \frac{1}{\alpha}\langle x^0_S, h_S \rangle + \|h_Z\|_1 \right] + \frac{1}{2\alpha}\|h\|_2^2$$

$$= \left[\|x^0\|_1 + \frac{1}{2\alpha}\|x^0\|_2^2\right] + \left[\langle \text{sign}(x^0_S), h_S \rangle + \frac{1}{\alpha}\langle x^0_S, h_S \rangle + \|h_Z\|_1 \right] + \frac{1}{2\alpha}\|h\|_2^2.$$

Since the last term of (48) is strictly positive, $x^0$ is the unique solution to (5), provided that

$$\langle \text{sign}(x^0_S), h_S \rangle + \frac{1}{\alpha}\langle x^0_S, h_S \rangle + \|h_Z\|_1 \geq 0.$$
Following the proof of Lemma 3.2 in [7] and from (46) and (47), we obtain
\[ \langle \text{sign}(x^*_S), h_S \rangle \geq -\frac{1}{4} (\|h_S\|_2 + \|h_Z\|_1) \quad \text{and} \quad \|h_Z\|_1 \geq \frac{1}{2} \|h_S\|_2, \]
which together with \( \alpha \geq 8 \|x^0\|_2 \) give
\[ \langle \text{sign}(x^*_S), h_S \rangle + \frac{1}{\alpha} \langle x^0_S, h_S \rangle + \|h_Z\|_1 \geq -\frac{1}{4} (\|h_S\|_2 + \|h_Z\|_1) - \frac{\|x^0_S\|_2}{\alpha} \|h_S\|_2 + \|h_Z\|_1 \]
\[ \geq -\frac{1}{4} \|h_S\|_2 + \frac{3}{4} \|h_Z\|_1 - \frac{1}{8} \|h_S\|_2 \]
\[ \geq \frac{3}{8} \|h_S\|_2 - \frac{3}{8} \|h_S\|_2 = 0. \]

Hence, \( x^0 + h \) gives a strictly worse objective (5) than \( x^0 \), so \( x^0 \) is the unique solution to (5).

**3.6. Matrix recovery guarantees.** It is fairly easy to extend the results above, except the “RIPless” analysis, to the recovery of low-rank matrices. Throughout this subsection, we let \( \sigma_i(X) \), \( i = 1, \ldots, m \), denote the \( i \)th largest singular value of matrix \( X \) of rank \( m \) or less, and let \( \|X\|_* := \sum_{i=1}^m \sigma_i(X) \), \( \|X\|_F := \left( \sum_{i=1}^m \sigma_i^2(X) \right)^{1/2} \), and \( \|X\|_2 = \sigma_1(X) \) denote the nuclear, Frobenius, and spectral norms of \( X \), respectively.

The extension is based on the following property of unitarily invariant matrix norms.

**Lemma 3.11 (see [23, Theorem 7.4.51]).** Let \( X \) and \( Y \) be two matrices of the same size. Any unitarily invariant norm \( \| \cdot \|_\phi \) satisfies
\[ \| \Sigma(X) - \Sigma(Y) \|_\phi \leq \| X - Y \|_\phi, \]
where \( \Sigma(X) = \text{diag}(\sigma_1(X), \ldots, \sigma_m(X)) \) and \( \Sigma(Y) = \text{diag}(\sigma_1(Y), \ldots, \sigma_m(Y)) \) are two diagonal matrices.

In particular, matrices \( X \) and \( Y \) obey
\[ \sum_{i=1}^m |\sigma_i(X) - \sigma_i(Y)| \leq \| X - Y \|_*, \]
and
\[ \sum_{i=1}^m (\sigma_i(X) - \sigma_i(Y))^2 \leq \| X - Y \|_F^2. \]

By applying (51), [36] shows that any sufficient conditions based on RIP and SSP of \( A \) for recovering sparse vectors by model (1) can be translated to sufficient conditions based on similar properties of \( A \) for recovering low-rank matrices by model (3). We can establish similar translations from model (12) to model (9) using both inequalities (51) and (52). Hence, we present the low-rank matrix recovery results only with the parts that are different from their vector counterparts.
Paper [35] presents the NSP condition for problem (3): all matrices \( X^0 \) of rank \( r \) or less can be exactly recovered by problem (3) from measurements \( b = A(X^0) \) if and only if all \( H \in \text{Null}(A) \setminus \{0\} \) satisfy

\[
\sum_{i=1}^{r} \sigma_i(H) < \sum_{i=r+1}^{m} \sigma_i(H).
\]

We can extend this result to problem (8) by applying inequalities (51) and (52).

**Theorem 3.12 (matrix NSP condition).** Assume that \( \|X^0\|_2 \) is fixed. Problem (8) uniquely recovers all matrices \( X^0 \) (with the specified \( \|X^0\|_2 \)) of rank \( r \) or less from measurements \( b = A(X^0) \) if and only if

\[
\left(1 + \frac{\|X^0\|_2}{\alpha}\right) \sum_{i=1}^{r} \sigma_i(H) \leq \sum_{i=r+1}^{m} \sigma_i(H)
\]

holds for all matrices \( H \in \text{Null}(A) \).

**Proof.** Sufficiency: Pick any matrix \( X^0 \) of rank \( r \) or less, and let \( b = A(X^0) \). For any nonzero \( H \in \text{Null}(A) \), we have \( A(X^0 + H) = A(X^0) = b \). By using (51) and (52), we have

\[
\|X^0 + H\|_* + \frac{1}{2\alpha} \|X^0 + H\|_F^2 \geq \|s(X^0) - s(H)\|_1 + \frac{1}{2\alpha} \|s(X^0) - s(H)\|_2^2
\]

\[
\geq \left[ \|X^0\|_* + \frac{1}{2\alpha} \|X^0\|_F^2 \right] + \left[ \sum_{i=r+1}^{m} \sigma_i(H) - \left(1 + \frac{\|X^0\|_2}{\alpha}\right) \sum_{i=1}^{r} \sigma_i(H) \right] + \frac{1}{2\alpha} \|H\|_F^2,
\]

where the second inequality follows from (19) by letting \( h = -s(H) \) and \( S = \{1, \ldots, r\} \) and noticing \( h_S = \sum_{i=1}^{r} \sigma_i(H) \) and \( h_Z = \sum_{i=r+1}^{m} \sigma_i(H) \).

For any nonzero \( H \in \text{Null}(A) \), \( \|H\|_F > 0 \). Hence, from (55) and (54), it follows that \( X^0 + H \) leads to a strictly worse objective than \( X^0 \). That is, \( X^0 \) is the unique solution to problem (8).

Necessity: For any nonzero \( H \in \text{Null}(A) \) obeying (54), let \( H = U\Sigma_V^T \) be the SVD of \( H \). Construct \( X^0 = -U\Sigma_1V^T \), where \( \Sigma_1 \) keeps only the largest \( r \) diagonal entries of \( \Sigma \) and sets the rest to 0. Scale \( X^0 \) so that it has the specified \( \|X^0\|_2 \). We have

\[
\|X^0 + tH\|_* + \frac{1}{2\alpha} \|X^0 + tH\|_F^2
\]

\[
= \|X^0\|_* + \frac{1}{2\alpha} \|X^0\|_F^2 + \left[ \sum_{i=r+1}^{m} \sigma_i(tH) - \left(1 + \frac{\|X^0\|_2}{\alpha}\right) \sum_{i=1}^{r} \sigma_i(tH) \right] + \frac{1}{2\alpha} \|tH\|_F^2
\]

for any \( t > 0 \). For \( X^0 \) to be the unique solution to (8), given \( b = A(X^0) \), we must have

\[
\left[ \sum_{i=r+1}^{m} \sigma_i(tH) - \left(1 + \frac{\|X^0\|_2}{\alpha}\right) \sum_{i=1}^{r} \sigma_i(tH) \right] + \frac{1}{2\alpha} \|tH\|_F^2 > 0
\]

for all \( t > 0 \). Hence, (54) is necessary. □
Paper [37] introduces the following RIP for matrix recovery.

**Definition 3.13 (matrix RIP).** Let $\mathcal{M}_r := \{X \in \mathbb{R}^{n_1 \times n_2} : \text{rank}(X) \leq r\}$. The RIP constant $\delta_r$ of linear operator $A$ is the smallest value such that

$$\delta_r \leq \frac{1}{\sqrt{2}}$$

holds for all $X \in \mathcal{M}_r$.

To uniformly recover all matrices of rank $r$ or less by solving (3), it is sufficient for $A$ to satisfy $\delta_{2r} < 0.1$ [37], which has been improved to the RIP with $\delta_{4r} < \sqrt{2} - 1$ in [8] and to $\delta_{2r} < 0.307$, as well as the RIPS involving $\delta_{3r}$, $\delta_{4r}$, and $\delta_{5r}$, in [30]. The algorithm SVP [25] provably achieves exact recovery if $\delta_{2r} < 1/3$.

Next, we present a stronger RIP-based condition for the unsmoothed problem (3), and then extend it to the smooth problem (8) without a proof.

**Theorem 3.14 (RIP condition for exact recovery by (3)).** Let $X^0$ be a matrix with rank $r$ or less. Problem (3) exactly recovers $X^0$ from measurements $b = A(X^0)$ if $A$ satisfies the RIP with $\delta_{2r} < 0.4931$.

The proof is a straightforward extension to the arguments in [29] using arguments in [36]; the interested reader can find it in the appendix. Next we present the result for the augmented model (8).

**Theorem 3.15 (RIP condition for exact recovery).** Let $X^0$ be a matrix with rank $r$ or less. The augmented model (8) exactly recovers $X^0$ from measurements $b = A(X^0)$ if $A$ satisfies the RIP with $\delta_{2r} < 0.4404$ and in (8) $\alpha \geq 10\|X^0\|_2$.

**Proof.** The proof of Theorem 3.14 in the appendix establishes that any $H \in \text{Null}(A)$ satisfies $\|H_0\|_F \leq \theta_{2r} \|\sum_{i \geq 1} H_i\|_*$. Hence, (54) holds if $(1 + \|X^0\|_2^2)^{-1} \geq \theta_{2r}$. The rest of the proof is similar to that of Theorem 3.3.

Skipping a proof similar to that of Theorem 3.5, we present the stable recovery result as follows.

**Theorem 3.16 (RIP condition for stable recovery).** Let $X^0 \in \mathbb{R}^{n_1 \times n_2}$ be an arbitrary matrix, and let $\sigma_i(X^0)$ be its $i$th largest singular value. Let $b := A(X^0) + n$, where $A$ is a linear operator and $n$ is an arbitrary noise vector. If $A$ satisfies the RIP with $\delta_{2r} \leq 0.3814$, then the solution $X^*$ of (9) with any $\alpha \geq 10 \cdot \|X^0\|_2$ satisfies the error bounds

$$\|X^* - X^0\|_* \leq C_1 \cdot \sqrt{2} \|n\|_2 + C_2 \cdot \hat{\sigma}(X^0),$$

$$\|X^* - X^0\|_F \leq \bar{C}_1 \cdot \|n\|_2 + (\bar{C}_2/\sqrt{r}) \cdot \hat{\sigma}(X^0),$$

where $\hat{\sigma}(X^0) := \sum_{i=r+1}^{\min\{n_1, n_2\}} \sigma_i(X^0)$ is the best rank-$r$ approximation error of $X^0$, $C_1$, $C_2$, $\bar{C}_1$, and $\bar{C}_2$ are given by formulas (33a)–(34b) in which $\theta_{2k}$ shall be replaced by $\theta_{2r}$ (given in (99)), and

$$C_3 := \frac{\alpha + \sigma_1(X^0)}{\alpha - \sigma_{r+1}(X^0)} \quad \text{and} \quad C_4 := \frac{2\alpha}{\alpha - \sigma_{r+1}(X^0)},$$

respectively.

Although there are few discussions on SSP for low-rank matrix recovery in the literature (cf. [14]), we present two SSP-based results without proofs.
Theorem 3.17 (matrix SSP condition for exact recovery). Let \( A : \mathbb{R}^{n_1 \times n_2} \to \mathbb{R}^m \) be a linear operator. Suppose there exists \( \Delta > 0 \) such that all nonzero \( H \in \text{Null}(A) \) satisfy
\[
\frac{\|H\|_*}{\|H\|_F} \geq \sqrt{\frac{m}{\Delta}}.
\]
Assume that \( \|X^0\|_2 \) and \( \alpha > 0 \) are fixed. If
\[
m \geq \left( 2 + \frac{\|X^0\|_2}{\alpha} \right)^2 r \Delta,
\]
then the null-space condition (54) holds for all \( H \in \text{Null}(A) \). Hence, (60) is sufficient for problem (8) to recover any matrices \( X^0 \) of rank \( r \) or less from measurements \( b = A(X^0) \).

Theorem 3.18 (matrix SSP condition for stable recovery). Assume that linear operator \( A : \mathbb{R}^{n_1 \times n_2} \to \mathbb{R}^m \) has the same property as it does in Theorem 3.17. Let \( X^0 \in \mathbb{R}^{n_1 \times n_2} \) be an arbitrary matrix. Let \( \alpha > 0 \) in problem (8). Define \( C_3 \) and \( C_4 \) in (59), which depend on \( \alpha \). If
\[
m \geq 4(1 + C_3)^2 r \Delta,
\]
then the solution \( X^* \) of (8) satisfies
\[
\|X^* - X^0\|_* \leq 4C_4 \hat{\sigma}(X^0),
\]
where \( \hat{\sigma}(X^0) := \sum_{i=r+1}^{\min\{n_1, n_2\}} \sigma_i(X^0) \) is the best rank-\( r \) approximation error of \( X^0 \).

4. Global linear convergence. Now we turn to studying the numerical properties of the linearized Bregman algorithm (LBreg) for the augmented model (5). In this section, we show that LBreg, as well as its two fast variants, achieves global linear convergence with no assumptions on the solution sparsity or aforementioned properties of matrix \( A \). First, we review the four equivalent forms of LBreg that have appeared in different papers. We start off with the dual gradient-descent iteration [40]: given a step size \( h > 0 \), \( y^{(0)} = 0 \), and \( k \) starting from 0,
\[
(63a) \quad y^{(k+1)} \leftarrow y^{(k)} - h \left( -b + \alpha A \text{ shrink}(A^T y^{(k)}) \right).
\]
The last term of (63a) is the gradient of the objective function of problem (10). By letting \( x^{(k)} := \alpha \text{ shrink}(A^T y^{(k)}) \), one obtains the “primal-dual” form
\[
(63b) \quad x^{(k+1)} \leftarrow \alpha \text{ shrink}(A^T y^{(k)}),
\]
\[
(63c) \quad y^{(k+1)} \leftarrow y^{(k)} + h(b - Ax^{(k+1)}).
\]
The same iteration is given in [41, 34, 4] as
\[
(63d) \quad x^{(k+1)} \leftarrow \alpha \text{ shrink}(v^{(k)}),
\]
\[
(63e) \quad v^{(k+1)} \leftarrow v^{(k)} + hA^T(b - Ax^{(k+1)}),
\]
where \( \mathbf{v}^{(k)} = \mathbf{A}^\top \mathbf{y}^{(k)} \). Finally, the name “linearized Bregman” comes from the iteration [41]

\[
\mathbf{x}^{(k+1)} \leftarrow \arg\min_\mathbf{x} D^p_{\ell_1}(\mathbf{x}, \mathbf{x}^{(k)}) + h\langle \mathbf{A}^\top (\mathbf{A}\mathbf{x} - \mathbf{b}), \mathbf{x} \rangle + \frac{1}{2\alpha}\|\mathbf{x} - \mathbf{x}^{(k)}\|_2^2,
\]

(63f)

\[
\mathbf{p}^{(k+1)} \leftarrow \mathbf{p}^{(k)} + h\mathbf{A}^\top (\mathbf{b} - \mathbf{A}\mathbf{x}^{(k)}) - \frac{1}{\alpha}(\mathbf{x}^{(k+1)} - \mathbf{x}^{(k)}),
\]

(63g)

where \( \mathbf{x}^{(0)} = \mathbf{p}^{(0)} = \mathbf{0} \) and the Bregman “distance” \( D^p_{\ell_1}(\cdot, \cdot) \) is defined as

\[
D^p_{\ell_1}(\mathbf{x}, \mathbf{y}) = f(\mathbf{x}) - f(\mathbf{y}) - \langle \mathbf{p}, \mathbf{x} - \mathbf{y} \rangle, \quad \text{where } \mathbf{p} \in \partial f(\mathbf{y}).
\]

The last two terms of (63f) replace the term \( \frac{1}{2\alpha}\|\mathbf{A}\mathbf{x} - \mathbf{b}\|_2^2 \) in the original Bregman iteration. Following [41], one can obtain (63d)–(63e) from (63f)–(63g) by setting \( \mathbf{v}^{(k)} = \mathbf{p}^{(k)} + h\mathbf{A}^\top (\mathbf{b} - \mathbf{A}\mathbf{x}^{(k)}) + \frac{x^{(k)}}{\alpha} \).

It is most convenient to work with (63a) due to its simplicity and gradient-descent interpretation. In the rest of this section, we let \( f(\mathbf{y}) \) be the objective function of (10) and have \( \nabla f(\mathbf{y}) = -\mathbf{b} + \alpha\mathbf{A} \text{shrink}(\mathbf{A}^\top \mathbf{y}) \).

4.1. Preliminary. In this subsection, we prove a few key results that will be used to prove the restricted strongly convex property in the next subsection.

Definition 4.1. Let \( \lambda_{\min}^+(\mathbf{S}) \) denote the minimum strictly positive eigenvalue of a nonzero symmetric matrix \( \mathbf{S} \), assuming its existence. Namely,

\[
\lambda_{\min}^+(\mathbf{S}) := \min\{\lambda_i(\mathbf{S}) : \lambda_i(\mathbf{S}) > 0\},
\]

where \( \{\lambda_i(\mathbf{S})\} \) is the set of eigenvalues of \( \mathbf{S} \).

Lemma 4.2. Let \( \mathbf{A} \) be a nonzero \( m \times n \) matrix. Let \( \mathbf{D} > 0 \) be an \( n \times n \) diagonal matrix with strictly positive diagonal entries. We have

\[
\lambda_{\min}^+(\mathbf{A}\mathbf{D}^\top) = \min_{\|\mathbf{A}\alpha\|_2 = 1} (\mathbf{A}\alpha)^\top (\mathbf{A}\mathbf{D}^\top) (\mathbf{A}\alpha).
\]

Proof. Let \( r = \text{rank}(\mathbf{A}) \geq 1 \). Since \( \text{rank}(\mathbf{A}\mathbf{D}^\top) = r \) and \( \mathbf{A}\mathbf{D}^\top \succeq 0, \mathbf{A}\mathbf{D}^\top \) has \( r \) strictly positive eigenvalues. Let \( \lambda > 0 \) be a positive eigenvalue, and let \( \mathbf{x} \) be its corresponding eigenvector. Since \( \mathbf{A}\mathbf{D}^\top \mathbf{x} = \lambda \mathbf{x} \), we see \( \mathbf{x} \in \text{Range}(\mathbf{A}) \) and can thus write \( \mathbf{x} = \mathbf{A}\alpha \lambda \). From this and \( \text{rank}(\mathbf{A}) = r \), the eigenvectors corresponding to the \( r \) strictly positive eigenvalues span \( \text{Range}(\mathbf{A}) \). Hence, (64) attains its minimum at the eigenvector \( \mathbf{A}\alpha \) corresponding to the eigenvalue \( \lambda_{\min}^+(\mathbf{A}\mathbf{D}^\top) \).

Next, we show that a constrained eigenvalue problem, which will appear in our proof of restricted strong convexity, has a strictly positive minimum objective.

Lemma 4.3. Let \( \mathbf{A} \) be a nonzero \( m \times n \) matrix, \( \mathbf{B} \) be an \( m \times \ell \) matrix, and \( \mathbf{D} > 0 \) be a diagonal matrix of size \( n \times n \). Let \( r := \text{rank}([\mathbf{A} \mathbf{B}]) - \text{rank}(\mathbf{A}), \) which satisfies \( 0 \leq r \leq \ell \). Let \( \mathbf{c} \) and \( \mathbf{d} \) be free vectors of sizes \( n \) and \( \ell \), respectively. The constrained eigenvalue problem

\[
v := \min \left\{ (\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d})^\top (\mathbf{A}\mathbf{D}^\top) (\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d}) : \|\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d}\|_2 = 1, \mathbf{B}^\top (\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d}) \leq 0, \|\mathbf{d}\|_2 \geq 0 \right\}
\]

\[
= \min \left\{ (\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d})^\top (\mathbf{A}\mathbf{D}^\top) (\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d}) : \|\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d}\|_2 = 1, (\mathbf{A}\mathbf{D}^\top) (\mathbf{A}\mathbf{c} + \mathbf{B}\mathbf{d}) \leq 0, \|\mathbf{d}\|_2 \geq 0 \right\}
\]
Introduce

We move \( c \) and \( d \). From this, we obtain

\[ B_d \]

Range(\( \mathbf{A} \)).

The result (66) reveals that (65) can go lower than (64) yet must remain strictly positive. From another perspective, if we ignore the constraints \( \mathbf{B}^\top (\mathbf{A}c + \mathbf{B}d) \leq 0 \) in (65), then we can choose \( c \) and \( d \geq 0 \) such that \( \mathbf{A}^\top (\mathbf{A}c + \mathbf{B}d) = 0 \) and thus have \( v = 0 \). (For example, if \( r > 0 \), we can choose any \( d \geq 0 \) so that \( \mathbf{B}d \notin \text{Range}(\mathbf{A}) \) and then choose \( c \) so that \( -\mathbf{A}c \) equals \( \mathbf{B}d \)'s projection on \( \text{Range}(\mathbf{A}) \); if \( r = 0 \), the case is trivial.) Therefore, the three constraints in (65) prevent \( \mathbf{A}^\top (\mathbf{A}c + \mathbf{B}d) \) from being 0. Those constraints will arise during the study of certain KKT systems.

**Proof of Lemma 4.3.** Let \( \mathbf{B} = [\mathbf{b}_1 \mathbf{b}_2 \cdots \mathbf{b}_\ell] \). If \( r = 0 \), then rank([\( \mathbf{A} \mathbf{B} \)]) = rank(\( \mathbf{A} \)) and thus \( \mathbf{A}c + \mathbf{B}d \in \text{Range}(\mathbf{A}) \). Since dropping the constraints \( \mathbf{B}^\top (\mathbf{A}c + \mathbf{B}d) \leq 0 \) and \( d \geq 0 \) from (65) does not increase its optimal objective, we have \( v \geq \lambda_{\min}^{++}(\mathbf{A}^\top \mathbf{A}) \geq v_{\min} > 0 \) from Lemma 4.2.

Now we consider the nontrivial case \( r > 0 \), i.e., \( \text{Range}([\mathbf{A} \mathbf{B}]) \supset \text{Range}(\mathbf{A}) \). Ignoring the constraints \( \mathbf{B}^\top (\mathbf{A}c + \mathbf{B}d) \leq 0 \), we can choose \( c \) and \( d \geq 0 \) such that \( \mathbf{A}^\top (\mathbf{A}c + \mathbf{B}d) = 0 \) and thus \( v = 0 \). (See the discussions before the proof, for example.) Therefore, the rest of the proof focuses on the role of these constraints.

The proof is based on induction. We will show later that as long as \( \text{Range}([\mathbf{A} \mathbf{B}]) \supset \text{Range}(\mathbf{A}) \), any minimizer \((\mathbf{c}^*, \mathbf{d}^*)\) of (65) makes at least one of the constraints \( \mathbf{B}^\top (\mathbf{A}c + \mathbf{B}d) \leq 0 \) active. (Minimizer \((\mathbf{c}^*, \mathbf{d}^*)\) exists for the following reason. Let \( \mathbf{s} = (\mathbf{A}c) \) and \( \mathbf{t} = (\mathbf{B}d) \) be the optimization variables instead of \( \mathbf{c} \) and \( \mathbf{d} \); then constraints \( d \geq 0 \) translate to \( \mathbf{t} \in \{\mathbf{B}d : d \geq 0\} \), which is a closed set. Since problem (65) has a compact, nonempty feasible set and a continuous objective function in terms of \( \mathbf{s} \) and \( \mathbf{t} \), there exist minimizer \((\mathbf{s}^*, \mathbf{t}^*)\) and thus \((\mathbf{c}^*, \mathbf{d}^*)\).) Without loss of generality, suppose this active constraint is \( \mathbf{b}_1^\top (\mathbf{A}c^* + \mathbf{B}d^*) = 0 \). From this, we obtain

\[
v = (\mathbf{A}c^* + \mathbf{B}d^*)^\top (\mathbf{A}^\top \mathbf{A})(\mathbf{A}c^* + \mathbf{B}d^*) = (\mathbf{A}c^* + \mathbf{B}d^*)^\top (\mathbf{A}^\top \mathbf{A} + \mathbf{b}_1^\top \mathbf{b}_1)(\mathbf{A}c^* + \mathbf{B}d^*).
\]

We move \( \mathbf{b}_1 \) “from \( \mathbf{B} \) to \( \mathbf{A} \)” by introducing new matrices \( \mathbf{A}_1 := [\mathbf{A} \mathbf{b}_1], \mathbf{B}_1 := [\mathbf{b}_2 \mathbf{b}_3 \cdots \mathbf{b}_\ell] \). Introduce

\[
\mathbf{D}_1 := \begin{bmatrix} \mathbf{D} & \mathbf{0} \\ \mathbf{0} & 1 \end{bmatrix}
\]

so \( (\mathbf{A}^\top \mathbf{A} + \mathbf{b}_1^\top \mathbf{b}_1) = (\mathbf{A}_1^\top \mathbf{A}_1) \). Furthermore, drop the constraints \( \mathbf{b}_1^\top (\mathbf{A}c^* + \mathbf{B}d^*) \leq 0 \) and \( d_1 \geq 0 \), and consider the resulting problem

\[
v_1 := \min_{c_1, d_1} \left\{ (\mathbf{A}_1^\top \mathbf{A}_1 + \mathbf{B}_1^\top \mathbf{B}_1)(\mathbf{A}_1 c_1 + \mathbf{B}_1 d_1) : \|\mathbf{A}_1 c_1 + \mathbf{B}_1 d_1\|_2 = 1, \mathbf{B}_1^\top (\mathbf{A}_1 c_1 + \mathbf{B}_1 d_1) \leq 0, d_1 \geq 0 \right\}.
\]
Problem (67) would have the same objective value as (65) if the active constraint $b_j^\top (Ac^* + Bd^*) = 0$ were present. As (67) does not have this constraint, we conclude that

$$v \geq v_1.$$  

We apply the same argument inductively to the subsequent problems: let

$$v_j := \min_{c_j, d_j} \left\{ (A_jc_j + Bjd_j)^\top (A_jD_jA_j^\top)(A_jc_j + Bjd_j) : \|A_jc_j + Bjd_j\|_2 = 1, B_j^\top (A_jc_j + Bjd_j) \leq 0, d_j \geq 0 \right\},$$

where each $A_j = [B_{j-1}, b_j]$, $B_j = [b_{j+1}, \ldots, b_p]$, and $D_j = [0_1^{\top}, D_{j-2}^{\top}, 0]$ for $j = 2, 3, \ldots, p$ until either $p = \ell$ (i.e., all $b_i$’s have been moved out of $B$) or $\text{Range}(A_p B_p) = \text{Range}(A_p)$ (i.e., the condition for the induction breaks down when $j$ reaches $p$). The former case occurs if $r = \ell$. In this case, we obtain empty $B_{p}$ and $d_{\ell}$, and thus

$$v_\ell = \min_{c_\ell} \left\{ (A_\ell c_\ell)^\top (A_\ell D_\ell A_\ell^\top)(A_\ell c_\ell) : \|A_\ell c_\ell\|_2 = 1 \right\}$$

and, from the induction,

$$v \geq v_1 \geq \cdots \geq v_\ell.$$

From $A_\ell D_\ell A_\ell^\top = ADA^\top + BB^\top$ and Lemma 4.2, it follows that

$$v_\ell = \lambda_{\min}^{+\ell}(ADA^\top + BB^\top).$$

The latter case (i.e., $j = p < \ell$) occurs if $0 < r < \ell$. In this case, $p \geq r$, and the induction gives $v \geq v_1 \geq \cdots \geq v_p$. From $\text{Range}(A_p B_p) = \text{Range}(A_p)$ and the same argument as at the beginning of this proof, we have $v_p \geq \lambda_{\min}^{+p}(A_p D_p A_p^\top)$. By the definition of $v_{\min}$, we have $\lambda_{\min}^{+p}(A_p D_p A_p^\top) \geq v_{\min}$ and thus $v \geq v_{\min} > 0$.

Hence, Lemma 4.3 is proved for all three cases: $r = 0$, $0 < r < \ell$, and $r = \ell$.

Finally, we establish the existence of an active constraint by showing that if $\text{Range}(A B) \supsetneq \text{Range}(A)$, every solution of the problem obtained by removing the constraints $B^\top (Ac + Bd) \leq 0$ from (65), namely,

$$\min_{c, d} \left\{ (Ac + Bd)^\top (ADA^\top)(Ac + Bd) : \|Ac + Bd\|_2 = 1, d \geq 0 \right\},$$

will violate $B^\top (Ac + Bd) \leq 0$. Since $\text{Range}(A B) \supsetneq \text{Range}(A)$, as argued above, one can choose $c$ and $d \geq 0$ such that $Ac + Bd \in \text{Null}(A)$ and thus $(Ac + Bd)^\top (ADA^\top)(Ac + Bd) = 0$. (See the discussions before the proof, for example.) Therefore, any solution $(\bar{c}, \bar{d})$ of (70) must attain the 0 objective, so

$$A^\top (Ac + Bd) = 0.$$ 

Suppose that

$$B^\top (Ac + Bd) \leq 0,$$
i.e., no constraint is violated. Then, from $\mathbf{d} \geq 0$, (72), and (71), it follows that

\begin{align}
(73) & \quad \mathbf{d}^\top \mathbf{B}^\top (\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}) \leq 0, \\
(74) & \quad \mathbf{c}^\top \mathbf{A}^\top (\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}) = 0,
\end{align}

so

$$
\|\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}\|_2^2 = \mathbf{d}^\top \mathbf{B}^\top (\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}) + \mathbf{c}^\top \mathbf{A}^\top (\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}) \leq 0,
$$

which contradicts the constraint $\|\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}\|_2 = 1$. Therefore, $\mathbf{B}^\top (\mathbf{A} \mathbf{c} + \mathbf{B} \mathbf{d}) \leq 0$ cannot hold, and at least one of these constraints must be violated. Clearly, this argument applies to problem (69) for $j = 1, 2, \ldots$, as long as $j \leq \ell$ and $\text{Range}([\mathbf{A}_j \ \mathbf{B}_j]) \supseteq \text{Range}([\mathbf{A}_j])$. □

**Lemma 4.4.** Let shrink be the shrinkage operator $\text{shrink}(s) = \text{sign}(s) \max\{|s| - 1, 0\}$. Then the inequality

$$
(75) \quad (s - s^*) \cdot (\text{shrink}(s) - \text{shrink}(s^*)) \geq \frac{|\text{shrink}(s^*)|}{|\text{shrink}(s^*)| + 2} (s - s^*)^2 \geq 0
$$

holds for $\forall s, s^* \in \mathbb{R}$. The first equality holds when $s = -\text{sign}(s^*)$.

**Proof.** The first inequality in (75) can be proved by elementary case-by-case analysis. The second one is trivial. □

### 4.2. Globally linear convergence.

In this subsection, we show that the LBreg iteration (63a), as a fixed–step size gradient-descent iteration for (10), generates globally linearly convergent sequences $\{\mathbf{y}^k\}$ and $\{\mathbf{x}^k\}$.

To do this, we need the following theorem from [40] with our modifications for better clarity. Below, we use the notion

$$
\text{shrink}(\mathbf{z}) := \text{shrink}_1(\mathbf{z}) = \mathbf{z} - \text{Proj}_{[-1,1]}(\mathbf{z}) = \text{sign}(\mathbf{z}) \max\{|\mathbf{z}| - 1, 0\},
$$

where $\text{sign}(-)$, $|\cdot|$, and $\max\{\cdot, \cdot\}$ are componentwise operations.

**Theorem 4.5.** Let $f$ denote the objective function of problem (10), and let $\mathbf{x}^*$ denote the solution of (5), which is unique since it has a strictly convex objective. Define coordinate sets $\mathcal{S}_+, \mathcal{S}_-, \mathcal{S}_0$ as the sets of positive, negative, and zero components of $\mathbf{x}^*$, respectively. Corresponding to $\mathcal{S}_+, \mathcal{S}_-, \mathcal{S}_0$, decompose

$$
\mathbf{A} = [\mathbf{A}_+, \mathbf{A}_-, \mathbf{A}_0],
\mathbf{x}^* = [\mathbf{x}^*_+; \mathbf{x}^*_-; \mathbf{x}^*_0].
$$

Then, the set of solutions of (10) is given by

\begin{align}
(76a) & \quad \mathcal{Y}^* = \{\mathbf{y}' \in \mathbb{R}^m : \alpha \text{shrink}(\mathbf{A}^\top \mathbf{y}') = \mathbf{x}^* \} \\
(76b) & \quad = \{\mathbf{y}' \in \mathbb{R}^m : \mathbf{A}_+^\top \mathbf{y}' - 1 = \alpha^{-1} \mathbf{x}^*_+, \ \mathbf{A}_-^\top \mathbf{y}' + 1 = \alpha^{-1} \mathbf{x}^*_-, \ -1 \leq \mathbf{A}_0^\top \mathbf{y}' \leq 1\},
\end{align}

which is a convex set. Furthermore, $\nabla f(\mathbf{y}') = 0$ for all $\mathbf{y}' \in \mathcal{Y}^*$.

**Proof.** Any $\mathbf{y}' \in \mathcal{Y}^*$ must satisfy the strong duality condition, namely, the primal objective equal to the dual objective: $-f(\mathbf{y}') = \|\mathbf{x}^*\|_1 + \frac{1}{2\alpha} \|\mathbf{x}^*\|_2^2$. From this and $\mathbf{A} \mathbf{x}^* = \mathbf{b}$, it is easy to derive $\alpha \text{shrink}(\mathbf{A}^\top \mathbf{y}') = \mathbf{x}^*$ using a case-by-case analysis on the sign of $\mathbf{x}^*_i$. Conversely,
since $\nabla f(y) = -b + A(\alpha \text{shrink}(A^T y))$ and $Ax^* = b$, any $y'$ obeying $\alpha \text{shrink}(A^T y') = x^*$ satisfies $\nabla f(y') = 0$. Then, $y' \in \mathcal{Y}^*$.

By the definition (76b), $\mathcal{Y}$ is a polyhedron, so it is convex. □

In general, the two sets of equality equations in (76b) do not define a unique $y^*$, so $\mathcal{Y}$ can include multiple solutions.

A typical tool for obtaining global convergence at a linear rate (or, global geometric convergence) is the strong convexity of the objective function. A function $g$ is strongly convex with a constant $c$ if it satisfies

$$
(77) \quad \langle y - y', \nabla f(y) - \nabla f(y') \rangle \geq c\|y - y'\|^2 \quad \forall y, y' \in \text{dom } f.
$$

Strong convexity, however, does not hold for our $f(y)$ since $\nabla f(y^*) = 0$ for all $y^* \in \mathcal{Y}$, while $\mathcal{Y}$ is not necessarily a singleton. Nevertheless, we establish the “restricted” strong convexity (78) below.

Lemma 4.6 (restricted strong convexity). Consider problem (10) with a nonzero $m$-by-$n$ matrix $A$ and nonzero vector $b$. Assume that $Ax = b$ are consistent. Let $\text{Proj}_{\mathcal{Y}^*}(y)$ denote the Euclidean projection of $y$ to the solution set $\mathcal{Y}^*$. The objective function $f$ of (10) satisfies

$$
(78) \quad \langle y - \text{Proj}_{\mathcal{Y}^*}(y), \nabla f(y) \rangle \geq \nu \|y - \text{Proj}_{\mathcal{Y}^*}(y)\|^2 \quad \forall y,
$$

where constant

$$
(79) \quad \nu = \lambda_A : \left( \min_{i \in \supp(x^*)} \frac{\alpha|x_i^*|}{|x_i^*| + 2\alpha} \right) > 0
$$

and $\lambda_A = \min \{\lambda_{\min}(CC^T) : C \text{ is a nonzero submatrix of } A \text{ of } m \text{ rows}\}$.

Note that if we let $y' = \text{Proj}_{\mathcal{Y}^*}(y)$, following from $\nabla f(y') = 0$, (78) becomes $\langle y - y', \nabla f(y) - \nabla f(y') \rangle \geq \nu \|y - y'\|^2$. Hence, (78) is the restriction of (77) to the specially chosen $y'$. However, this will be enough for global linear convergence.

Proof of Lemma 4.6. Since $Ax = b$ is consistent, problem (5) has a unique solution $x^*$, so $\mathcal{Y}$ is well defined and nonempty. If $y \in \mathcal{Y}$, then $y = \text{Proj}_{\mathcal{Y}^*}(y)$ and thus (78) holds trivially. To show (78) for $y \notin \mathcal{Y}$, we shall consider

$$
(80) \quad \min \left\{ \frac{\langle y - y', \nabla f(y) - \nabla f(y') \rangle}{\langle y - y', y - y' \rangle} : y - y' \neq 0, y' = \text{Proj}_{\mathcal{Y}^*}(y) \right\}.
$$

The proof is divided into three parts. The first part works out $y' = \text{Proj}_{\mathcal{Y}^*}(y)$ and expresses $y - y'$ in terms of submatrices of $A$. The second part establishes $\langle y - y', \nabla f(y) - \nabla f(y') \rangle \geq (y - y')^T M(y - y')$, where $M \succeq 0$ also depends on submatrices of $A$. The last part invokes Lemma 4.3 to obtain a strictly positive lower bound for (80). Most of the effort is to decompose $A$ into the submatrices and understand how they contribute to $y - y'$ and $\nabla f(y) - \nabla f(y')$.

Part 1. By definition, $y' = \text{Proj}_{\mathcal{Y}^*}(y)$ is the solution of

$$
(81) \quad \min_{\tilde{y}} \left\{ \frac{1}{2} \|	ilde{y} - y\|^2 : \tilde{y} \in \mathcal{Y} \right\}.
$$
Hence, \( y' \) satisfies the KKT conditions of (81). Using the expression of \( \mathcal{Y}' \) in (76b), these conditions are

\[
\begin{align*}
(82a) & \quad y - y' = A_+ \lambda_+ + A_- \lambda_- + A_0 (u - \ell), \\
(82b) & \quad y' \in \mathcal{Y}'', \\
(82c) & \quad \ell, u \geq 0, \\
(82d) & \quad (1 - A_0^\top y')^\top u + (1 + A_0^\top y')^\top \ell = 0,
\end{align*}
\]

where \( \lambda_+ \) and \( \lambda_- \) are the Lagrange multipliers for the two equality conditions in (76b) and \( \ell \) and \( u \) are those for the first and second inequality conditions in (76b), respectively. Equation (82d) is the so-called complementarity condition, which together with (82c) gives the following three cases for \( \forall i \in S_0 \):

\[
\begin{align*}
(83) & \quad \ell_i = 0, \ u_i = 0; \quad \text{if } u_i > 0, \text{ then } A_i^\top y' = 1, \ \ell_i = 0; \quad \text{if } \ell_i > 0, \text{ then } A_i^\top y' = -1, \ u_i = 0.
\end{align*}
\]

Part 2. Let \( A_\pm = [A_+, A_-] \). We first argue that \( A_\pm \) is a nonzero submatrix of \( A \). Since \( A \) and \( b \) are both nonzero, the solution \( x^* \) to problem (5) is nonzero. If some column \( a_i \) of \( A \) is a zero vector, then \( x_i \) is free from the constraints \( Ax = b \) and thus \( x_i^* = 0 \). Hence, all the columns of \( A_\pm \) are nonzero vectors.

From \( \nabla f(y) = -b + \alpha A \text{ shrink}(A^\top y) \) and \( 0 = \nabla f(y') = -b + \alpha A \text{ shrink}(A^\top y') \), we obtain

\[
\begin{align*}
(84a) & \quad (y - y', \nabla f(y)) = (y - y', \nabla f(y) - \nabla f(y')) = \alpha (A^\top y - A^\top y', \text{ shrink}(A^\top y) - \text{ shrink}(A^\top y')) \\
(84b) & \quad = \alpha (A_+^\top y - A_-^\top y', \text{ shrink}(A_+^\top y) - \text{ shrink}(A_-^\top y')) \\
(84c) & \quad + \alpha (A_0^\top y - A_0^\top y', \text{ shrink}(A_0^\top y) - \text{ shrink}(A_0^\top y')).
\end{align*}
\]

By definition, every component of \( \text{ shrink}(A_+^\top y') = \alpha^{-1} x_+^* \) is nonzero, and all components of \( \text{ shrink}(A_0^\top y') = \alpha^{-1} x_0^* \) are zero. For this reason, we deal with (84b) and (84c) separately.

Applying inequality (75) to (84b), we can “remove” the “shrink” operators for (84b) as follows:

\[
\begin{align*}
\alpha (A_+^\top y - A_-^\top y', \text{ shrink}(A_+^\top y) - \text{ shrink}(A_-^\top y')) \\
= \alpha \sum_{i \in S_\pm} (a_i^\top y - a_i^\top y') \cdot (\text{ shrink}(a_i^\top y) - \text{ shrink}(a_i^\top y')) \\
\geq \alpha \sum_{i \in S_\pm} \frac{\alpha^{-1} |x_i^*|}{\alpha^{-1} |x_i^*| + 2} \cdot (a_i^\top y - a_i^\top y')^2 \\
= \alpha (y - y')^\top \hat{D} A_\pm \hat{D} A_\pm (y - y'),
\end{align*}
\]

where \( \hat{D} := \text{diag}(\alpha^{-1} |x_i^*|)_{i \in \text{supp}(x^*)} \geq 0 \). Equation (85) alone is not enough to bound (80) from zero since \( A_\pm \) can have more columns than rows and \( A_\pm \hat{D} A_\pm \) can be rank deficient. So, we need to include (84c) in the analysis, and we begin with a decomposition of the involved matrix \( A_0 \):

\[
A_0 = [A_1 \ A_2 \ A_3 \ A_4 \ A_5]
\]
according to the criteria

\begin{align}
(86a) & \quad y - y' = A_\pm \lambda_\pm + A_1 u_1 + A_2 u_2 - A_3 \ell_3 - A_4 \ell_4, \text{ where } u_1, u_2, \ell_3, \ell_4 > 0, \\
(86b) & \quad A_1^T y > +1, \\
(86c) & \quad A_2^T y \leq +1, \\
(86d) & \quad A_3^T y < -1, \\
(86e) & \quad A_4^T y \geq -1.
\end{align}

Equations (86) mean the following: (i) the projected point \( y' \) is actively confined by the boundaries of \( \mathcal{Y}^* \) involving \([A_1, A_2, A_3, A_4]\) (cf. the last term of (76b)); (ii) \( A_5 \) does not contribute to \( y - y' \); (iii) by applying (83) and (86b)–(86e), we get \( A_1^T y' = 1, A_3^T y' = -1 \) and can thus simplify the components of (84c) involving \( A_1 \) and \( A_3 \) as follows:

\begin{align}
(87a) & \quad \text{shrink}(A_1^T y) - \text{shrink}(A_1^T y) = \text{shrink}(A_1^T y) = A_1^T y - 1 = A_1^T y - A_1^T y', \\
(87b) & \quad \text{shrink}(A_3^T y) - \text{shrink}(A_3^T y) = \text{shrink}(A_3^T y) = A_3^T y + 1 = A_3^T y - A_3^T y'.
\end{align}

Now we “drop” the components of (84c) involving \( A_2, A_4, \) and \( A_5 \) as follows: from (75), it follows that \( \langle A_2^T y - A_2^T y', \text{shrink}(A_2^T y) - \text{shrink}(A_2^T y') \rangle \geq 0 \) for \( i = 2, 4, 5 \). Hence,

\begin{align}
\alpha\langle A_2^T y - A_2^T y', \text{shrink}(A_2^T y) - \text{shrink}(A_2^T y') \rangle \\
= \alpha \sum_{i=1}^{5} \langle A_i^T y - A_i^T y', \text{shrink}(A_i^T y) - \text{shrink}(A_i^T y') \rangle \\
\geq \alpha \sum_{i=1,3} \langle A_i^T y - A_i^T y', \text{shrink}(A_i^T y) - \text{shrink}(A_i^T y') \rangle \\
\alpha = \langle y - y', \nabla f(y) \rangle \geq \alpha(A\hat{c} + B\hat{d})^T(A\hat{D}\hat{A}^T)(A\hat{c} + B\hat{d}).
\end{align}

However, (89) is still not enough to bound (80) from zero since \( \hat{A}\hat{D}\hat{A}^T \) may still be rank deficient.

Part 3. To bound (80), we now include the “dropped” parts of \( A \) and apply Lemma 4.3. From (83), we have \( A_2^T y = 1 \) and \( A_4^T y' = -1 \), and further, from (86c) and (86e),

\begin{align}
1 & \geq A_2^T y = A_2^T y' + A_2^T (y - y') = +1 + A_2^T (A\hat{c} + B\hat{d}), \\
-1 & \leq A_4^T y = A_4^T y' + A_4^T (y - y') = -1 + A_4^T (A\hat{c} + B\hat{d}),
\end{align}

or, written compactly,

\begin{align}
\hat{B}^T(A\hat{c} + B\hat{d}) \leq 0.
\end{align}
is called globally Q-linear if there exists
for all

where

is a vector and

is an m-by-p submatrix of

. Therefore, we have

\[
\frac{\langle y - y', \nabla f(y) \rangle}{\langle y - y', y - y' \rangle} \geq \alpha \cdot \min \{ \min(D)_{ii} \} \cdot \min \{ \lambda_{\text{A}}^{+}(CC^T) : C \text{ is a nonzero submatrix of A of m rows} \}
\]

\[
\geq \left( \min \{ \min(D)_{ii} \} \frac{\alpha |x^*_i|}{|x^*_i| + 20} \right) \cdot \lambda_{\text{A}}
\]

= \nu.

**Remark 4.** If the entries of A are in general positions, i.e., any m distinct columns of A are linearly independent, or, in other words, A has completely full rank \([27]\), then all m-by-m submatrices of A have full rank and thus \(\lambda_{\text{A}} = \{ \lambda_{\text{min}}(CC^T) : C \text{ is an m-by-m submatrix of A} \}\). This is often the case when those entries are samples from i.i.d. sub-Gaussian distributions, or the columns of A are data vector independent of one another. In general, the submatrix \(C^*\) achieving the minimum \(\lambda_{\text{A}}\) has the maximum number of independent columns; i.e., it contains \(r\) columns from A where \(r = \text{rank}(A)\).

With the restricted strong convexity property, we next show the main convergence result with the help of the standard notion of point-to-set distance,

\[
\text{dist}(z, Z) := \min_{z'} \{ \| z - z' \|_2 : z' \in Z \},
\]

where z is a vector and Z is a set of vectors. By convention, the convergence dist\((z^k, Z) \to 0\) is called globally Q-linear if there exists \(\mu \in (0, 1)\) such that dist\((z^{k+1}, Z)/\text{dist}(z^k, Z) \leq \mu\) for all \(k\), and the convergence \(s^k \to 0\) is called globally R-linear if there exists a globally Q-linear converging sequence \(t^k \to 0\) such that \(|s^k| \leq |t^k|\). Unlike Q-linear convergence, R-linear convergence does not require \(|s^k|\) to be monotonic in \(k\).

**Theorem 4.7.** Consider problem \((10)\) with a nonzero m-by-n matrix A and a nonzero vector b. Assume that \(Ax = b\) are consistent. Let f be the objective function of problem \((10)\), and let \(f^*\) be the optimal objective value. The linearized Bregman iteration \((63a)\) starting from any \(y^{(0)} \in \mathbb{R}^m\) with step size

\[
0 < h < 2\nu/(\alpha^2||A||^4),
\]

where the strong convexity constant \(\nu\) is given in \((79)\), generates a globally Q-linearly converging sequence \(\{y^{(k)}, k \geq 1\}\) obeying

\[
\text{dist}(y^{(k)}, \mathcal{Y}^*) \leq (1 - 2h\nu + h^2\alpha^2||A||^2)^{k/2} \text{dist}(y^{(0)}, \mathcal{Y}^*),
\]

where \(\mathcal{Y}^*\) is the set of solutions to the problem.
where \( \mathcal{Y}^* \) is given in (76). The objective value sequence converges \( R \)-linearly as

\[
(92) \quad f(y^{(k)}) - f^* \leq \frac{L}{2} \left( 1 - 2h\nu + h^2\alpha^2 \|A\|_2^4 \right)^k \text{dist}^2(y^{(0)}, \mathcal{Y}^*).
\]

Furthermore, \( \{x^{(k)}\} \) is a globally \( R \)-linear converging sequence since

\[
(93) \quad \|x^{(k+1)} - x^*\|_2 \leq \alpha \|A\|_2 \cdot \text{dist}(y^{(k)}, \mathcal{Y}^*).
\]

**Proof.** For each \( k \), let \( y^{(k)} := \text{Proj}_{\mathcal{Y}^*}(y^{(k)}) \). Hence, \( \text{dist}(y^{(k)}, \mathcal{Y}^*) = \|y^{(k)} - y^{(k)}\|_2 \). Using this projection property, we have

\[
(94a) \quad \|y^{(k+1)} - y^{(k+1)}\|_2^2 \leq \|y^{(k+1)} - y^{(k)}\|_2^2
\]

\[
(94b) \quad = \|y^{(k)} - y^{(k)} - h\nabla f(y^{(k)})\|_2^2
\]

\[
(94c) \quad = \|y^{(k)} - y^{(k)}\|_2^2 - 2h\langle \nabla f(y^{(k)}), y^{(k)} - y^{(k)} \rangle + h^2\|\nabla f(y^{(k)}) - \nabla f(y^{(k)})\|_2^2
\]

\[
(94d) \quad \leq (1 - 2h\nu) \|y^{(k)} - y^{(k)}\|_2^2 + h^2\|A\|_2^2 \|\nabla f(y^{(k)}) - A y^{(k)}\|_2^2
\]

\[
(94e) \quad \leq (1 - 2h\nu) \|y^{(k)} - y^{(k)}\|_2^2 + h^2\|A\|_2^2 \|y^{(k)} - A y^{(k)}\|_2^2
\]

\[
(94f) \quad \leq (1 - 2h\nu + h^2\alpha^2 \|A\|_2^4) \|y^{(k)} - y^{(k)}\|_2^2,
\]

where we have used the nonexpansive property of the shrinkage operator (cf. [22]). Hence, we obtain (91).

To get (92), we recall for any convex \( f \) with \( L \)-Lipschitz \( \nabla f \), \( f(y) - f(x) \leq \langle \nabla f(x), y - x \rangle + \frac{L}{2} \|y - x\|_2^2 \) (see Theorem 2.1.5 in [32]). Let \( y = y^{(k)} \) and \( x = y^{(k)} \). We have \( f(y^{(k)}) = f^* \), \( \nabla f(y^{(k)}) = 0 \), and from (91),

\[
f(y^{(k)}) - f^* \leq \frac{L}{2} \|y^{(k)} - y^{(k)}\|_2^2 \leq \frac{L}{2} \left( 1 - 2h\nu + h^2\alpha^2 \|A\|_2^4 \right)^k \text{dist}^2(y^{(0)}, \mathcal{Y}^*),
\]

which shows (92). When \( 0 < h < 2\nu/(\alpha^2 \|A\|_2^4) \), we have \( (1 - 2h\nu + h^2\alpha^2 \|A\|_2^4) < 1 \). Due to (63b), (76a), and the nonexpansiveness of shrink(\( \cdot \)), we get

\[
(95a) \quad \|x^{(k+1)} - x^*\|_2 \leq \alpha \|A\|_2 \cdot \|y^{(k)} - y^{(k)}\|_2
\]

\[
(95b) \quad \leq \alpha \|A\|_2 \cdot \|y^{(k)} - y^{(k)}\|_2
\]

which gives (93). \( \blacksquare \)

**Remark 5.** If we set \( h = \nu/(\alpha^2 \|A\|_2^4) \), then the geometric decay factor \( (1 - 2h\nu + h^2\alpha^2 \|A\|_2^4) = (1 - \nu^2/(\alpha^2 \|A\|_2^4)) \). Hence, we find the convergence rate affected by \( \nu, \alpha, \) and \( \|A\|_2 \). From the definition of \( \nu \) in (79), we get

\[
\text{decay factor} = 1 - \frac{\nu^2}{\alpha^2 \|A\|_2^4} = 1 - \omega^2 \cdot \kappa^2,
\]
where
\[
\omega := \min_{i \in \text{supp}(x^*)} \frac{|x^*_i|/\alpha}{2 + |x^*_i|/\alpha},
\]
\[
\kappa := \min \left\{ \frac{\lambda_{\min}(CC^T)}{\lambda_{\max}(AA^T)} : C \text{ is a nonzero submatrix of } A \text{ of } m \text{ rows} \right\}.
\]
The constant \( \kappa \) is similar to the “condition number” of \( A \). Let \( r^* = \left( \frac{\max_{i \in \text{supp}(x^*)} x^*_i}{\min_{i \in \text{supp}(x^*)} x^*_i} \right) \) denote the dynamic range of \( x^* \). If we set \( \alpha = C\|x^*\|_\infty \), then
\[
\omega = (1 + 2Cr^*)^{-1}.
\]
For recovering a sparse vector, recall that both the simulations in section 3.1 and the analysis in section 3 show that if \( x^* \) has faster decaying nonzero entries, \( C \) can be set smaller. So, when \( r^* \) is large, one can choose a small \( C \) to counteract.

The proved rate of convergence is quite conservative. The dependence on the solution dynamic range is due to (85), which considers the worst case of (75), yet when this worst case happens, the inequality between (94d) and (94e) can be improved due to properties of the shrinkage operator. In addition, our analysis on the global rate does not exploit the possibility that the algorithm may reach the optimal active set in a finite number of iterations and then exhibit faster linear convergence, typically at a rate depending only on the active set of columns of \( A \) and independent of the solution’s dynamic range.

The step size \( h \leq 2\nu/(\alpha^2 \|A\|_4^2) \) is also very conservative. As one will see in the simulation results in the next section, classical techniques for gradient descents such as line search can significantly accelerate the convergence.

4.3. Extensions to two faster variants of LBreg. We extend the linear convergence results to two variants of LBreg (iteration (63)) that can run significantly faster than LBreg: BB-line-search [40] and kicking [34]. The former dynamically sets the step size \( h \) in (63) by the Barzilai–Borwein method with nonmonotone line search using techniques from [43]. The latter is a simple add-on to iteration (63) to consolidate a sequence of consecutive iterations in which \( x^k \) is unchanged. If \( x^k = \cdots = x^{k+j} \), [34] shows that \( y^k, \ldots, y^{k+j} \) stay on the same line, so it is easy to skip all the intermediate iterations and go directly to the end of the line.

Obviously, since kicking skips only certain LBreg iterations, it maintains global linear convergence. On the other hand, given strong convexity, Theorems 3.1 and 3.2 of [43] show that BB-line-search also enjoys global linear convergence (though the results are weakened to the R-linear convergence of \( Ax^{(k)} - b \) in our case); it is not difficult to verify that the theorem and its proof remain valid given only restricted strong convexity.\(^1\)

\(^1\)In [43], Theorem 3.1 relies on its inequality (3.4), which in turn requires inequalities (3.3) and (3.2) to hold between a current point and its projection to the solution set. Equation (3.2) in [43] is precisely our (77). Theorem 3.2 needs (3.12) and in turn (3.11). Equation (3.11) is obtained from (3.1) restricted to between a current point and its projection to the solution set, which can be proved by assuming (3.2) or our (77).
4.4. Numerical demonstration. We present the results of simple tests to demonstrate the convergence of three algorithms: the original LBreg iteration (63), kicking [34], and BB-line-search [43, 40]. Their numerical efficiency and properties have been previously studied in papers [34, 39, 24] and are not the focus of this paper, so we merely use two examples to illustrate global linear convergence. We generated two compressive sensing tests where both tests had signals $x^0$ with 512 entries, out of which 50 were nonzero and sampled from the standard Gaussian distribution (for Figure 2) or from the Bernoulli distribution (for Figure 3). Both tests had the same sensing matrix $A$ with 256 rows and entries sampled from the standard Gaussian distribution. We set $\alpha = 10 \|x^0\|_\infty$ in each test and stopped all three algorithms upon $\|\nabla f(y)\|_2 < 10^{-6}$. The iterative errors $\|x^k - x^*\|_2$ and $\|y^k - y^*\|_2$ of the three algorithms are depicted in Figures 2 and 3. In both tests, the original version was the slowest. Besides the obvious speed differences, we observe that $\{x^{(k)}\}$ were not monotonic; there were sets of consecutive iterations in which $x^{(k)}$ did not change or fluctuate. Indeed, it is impossible to improve its R-linear convergence to Q-linear convergence. In addition, unlike the other two algorithms, $BB$-line-search has nonmonotonic $\{y^{(k)}\}$, which converges R-linearly instead of Q-linearly.

The convergence appears to have different stages. The early-middle stage has much slower convergence than the final stage.

Comparing the results of two tests, the convergence was faster on the Bernoulli sparse signal than on the Gaussian sparse signal. Since the two tests used the same sensing matrix $A$ and the same sparsity, the main reason should be the dynamic range of the signals. A smaller dynamic range leads to faster convergence, which matches our theoretical result on the convergence rate.

Appendix.

Proof of Theorem 3.14. We establish the theorem by showing that (53) holds for any $H \in \text{Null}(A) \setminus \{0\}$.

Based on SVD $H = \sum_{i=1}^m \sigma_i(H) u_i v_i^T$, where $\sigma_i(H)$ is the $i$th largest singular value of $H$, we...
decompose $H = H_0 + H_1 + H_2 + \cdots$, where $H_0 = \sum_{i=1}^{r} \sigma_i(H)u_i v_i$, $H_1 = \sum_{i=r+1}^{2r} \sigma_i(H)u_i v_i$, $H_2 = \sum_{i=2r+1}^{3r} \sigma_i(H)u_i v_i$, \ldots. Following these definitions, condition (53) can be equivalently written as

$$\|H_0\|_* < \sum_{i \geq 1} \|H_i\|_*.$$  

From $H \neq 0$ and the definition of $H_0$, we know that $H_0 \neq 0$ and thus $A(H_0) \neq 0$ due to the RIP of $A$. From $A(H) = 0$ and $A(H_0) \neq 0$, it follows that $A(\sum_{i \geq 1} H_i) \neq 0$ and thus $\sum_{i \geq 1} H_i \neq 0$. Therefore, $\sum_{i \geq 1} \|H_i\|_* > 0$, and we can define $t := \|H_1\|_*/(\sum_{i \geq 1} \|H_i\|_*) > 0$ and $\rho := \|H_0\|_*/(\sum_{i \geq 1} \|H_i\|_*) > 0$.

Next, we present two inequalities without proofs (the interested reader can verify them following the proofs of Lemmas 2.3 and 2.4 in [29]):

$$\frac{1 - \delta_2(r^2 + t^2)}{r} \left( \sum_{i \geq 1} \|H_i\|_* \right)^2 \leq \|A(H_0 + H_1)\|_2^2,$$

$$\frac{t(1-t) + \delta_2r(1-3t/4)^2}{r} \left( \sum_{i \geq 1} \|H_i\|_* \right)^2 \geq \left\| A \left( \sum_{i \geq 2} H_i \right) \right\|_2^2.$$

Since $A(H_0 + H_1) + A(\sum_{i \geq 2} H_i) = A(H) = 0$, the two right-hand sides of (98) equal each other. Hence,

$$\frac{1 - \delta_2(r^2 + t^2)}{r} \left( \sum_{i \geq 1} \|H_i\|_* \right)^2 \leq \frac{t(1-t) + \delta_2r(1-3t/4)^2}{r} \left( \sum_{i \geq 1} \|H_i\|_* \right)^2.$$
and thus
\[
\rho^2 \leq \frac{t(1-t) + \delta_{2r}(1-3t/4)^2 - (1-\delta_{2r})t^2}{1-\delta_{2r}}.
\]
Or, after a simple calculation of the maximum of \( t \in [0,1] \),
\[
\rho \leq \sqrt{\frac{4(1+5\delta_{2r} - 4(\delta_{2r})^2)}{(1-\delta_{2r})(32 - 25\delta_{2r})}} =: \theta_{2r}.
\]
If \( \delta_{2r} < (77 - \sqrt{1337})/82 \approx 0.4931 \), then \( \theta_{2r} < 1 \) and thus \( \rho < 1 \). By definition, we get (97) and (53).

Acknowledgments. We thank Hui Zhang, who was visiting Rice University from National University of Defense Technology, for his suggestions on the RIPless analysis, as well as Profs. Shiqian Ma and Qing Ling for valuable discussions. We also thank the anonymous referees for numerous suggestions and corrections that have helped improve this manuscript.
