SOME DISTANCE MEASURES
AND THEIR USE IN FEATURE SELECTION

by P. Papantoni-Kazakos
Electrical Engineering
Rice University

Abstract
The Bhattacharyya, I-divergence, Vasershtein, variational and Lévy distances are evaluated, compared and used for the reduction of n data to one feature. This reduction is obtained through a restricted linear transformation and the original data are assumed to be originating from two different jointly Gaussian classes.

It is found that the Bhattacharyya, I-divergence and Vasershtein distances give the same "optimal" linear transformation that applied on the original n data result in one feature with maximum possible distance between classes.

The distortion measures considered in the Vasershtein distance are $|x-y|$ and $(x-y)^2$. For the same distance measures and classes with equal covariances the Lévy distance results in the same "optimal" linear transformation.

This work was supported by the Air Force Grant AFOSR 77-3156
I. Introduction

Distances between probability measures have been used as valuable evaluation and optimization criteria in signal selection [8], pattern recognition [22], universal coding [16, 18], and statistical robustness [21].

The choice of the proper distance must be the result of a carefully weighted decision, where both the calculability and the power of the distance are considered.

An additional factor that is important for the choice of the proper distance in statistically ill-defined environments is the sensitivity of the distance to the changes of the underlined measures.

In section 3 of this paper some comparative evaluation between Bhattacharyya, I-divergence, Vasershtein, variational and Lévy distances is presented.

In section 4, the above distances are used for the linear reduction of n data coming from two Gaussian populations, to one feature.

2. Preliminaries

Let $(\Omega, \mathcal{G}, \mu)$ be a separable, complete measure space, where $\mathcal{G}$ is a $\sigma$-algebra of sets in $\Omega$ and $\mu$ is the measure. Let us now define two different measures $\mu_1$, $\mu_2$ in $(\Omega, \mathcal{G})$ such that $\mu_1(\Omega) = \mu_2(\Omega)$.

If $A, B$ are set-members of the $\sigma$-algebra $\mathcal{G}$, and if $\rho(A, B)$ is a penalty function, or distortion measure defined on $\mathcal{G}$, then the Prokhorov and Vasershtein distances between the two measures $\mu_1$, $\mu_2$ are defined as follows:

Prokhorov distance:

$$d_{P, \rho}(\mu_1, \mu_2) = \inf\{\epsilon : \mu_1(A) \leq \mu_2(\cup B : B \in \mathcal{G}; \rho(A, B) \leq \epsilon) + \epsilon, \mu_2(A) \leq \mu_1(\cup B : B \in \mathcal{G}; \rho(A, B) \leq \epsilon) + \epsilon; \forall \epsilon \in \mathcal{G}\}$$

(1)
Vasershtein distance:
\[ d_{\mathcal{V}, \rho}(\mu_1, \mu_2) \inf_{\mathcal{E}(\ldots)} \left\{ \rho(A, B) \right\} \]
\[ \text{all joint} \]
measures \( r(A, B); \mu_1(A); \mu_2(B) \) marginals

The distortion measure considered is incorporated in the definition of the Prokhorov and Vasershtein distances. Also, the Prokhorov distance is very sensitive to the changes of the \( \mu_1, \mu_2 \) measures, while for some choices of distortion measure \( \rho(\ldots) \), the Vasershtein distance is only a function of second order statistical characteristics (as shown in [16] and discussed in section 3). Finally, while the Prokhorov distance is bounded from above by \( \mu_1(\Omega); \mu_2(\Omega) \), the Vasershtein distance is bounded only if the distortion measure \( \rho(A, B) \) is, for all \( A, B \in \mathcal{G} \).

If the distortion measure \( \rho(A, B) \) is a metric and is such that \( \rho(A, A) = 0 \), then it was shown by Dobrushin ([13] pp 496) that \( d_{\mathcal{V}, \rho}(\mu_1, \mu_2) \) is also a metric and \( d_{\mathcal{V}, \rho}(\mu_1, \mu_2) = 0 \) if and only if \( \mu_1 = \mu_2 \). The Prokhorov distance has the same properties for any \( \rho(\ldots) \) choice. In Dobrushin the relationship:
\[ d_{\mathcal{V}, \rho}(\mu_1, \mu_2) \leq \left[ d_{\mathcal{P}, \rho}(\mu_1, \mu_2) \right]^2 \]
is also stated. A formal proof of this relationship is given in appendix A.

If the space \( \Omega \) is a Euclidean space, and \( f_1, f_2 \) are cumulative distributions, the Prokhorov distance reduces to the Lévy distance. For \( \Omega \) the \( x \)-real line, and for \( \mu_1, \mu_2 \) being the one-dimensional cumulative distributions \( F_1(x), F_2(x) \) correspondingly, the Lévy distance is given by the following expression:
\[ d_{\mathcal{L}, \rho}(F_1, F_2) \inf \left\{ \epsilon : F_2 \left( \min(y; \rho(x, y) \leq \epsilon) \right) - \epsilon \leq F_1(x) \leq F_2 \left( \max(y; \rho(x, y) \leq \epsilon) \right) + \epsilon \forall x \right\} \]
The Lévy distance has the same properties with the Prokhorov distance. Specifically, it is a metric, it lies between 0 and 1 and it is equal to zero if and only if \( F_1 = F_2 \). It is also obviously true that the Lévy distance is very sensitive to distribution \( F_1, F_2 \) changes.
A set of distances that are also very sensitive to distribution changes and are defined on Euclidean spaces are the Kolmogorov, variational, I-divergence and Bhattacharyya. The three last assume existence of non-cumulative distributions (density functions). If we concentrate on one-dimensional Euclidean spaces and denote by $f_1, f_2$ the densities of $F_1, F_2$ correspondingly, we denote:

Kolmogorov distance:

$$d_K(F_1, F_2) = \sup | F_1(x) - F_2(x) |$$

Variational distance:

$$d_V(f_1, f_2) = \int_{-\infty}^{\infty} | f_1(x) - f_2(x) | dx$$

I-divergence distance:

$$d_I(f_1, f_2) = \frac{1}{2} \int_{-\infty}^{\infty} \left[ f_1(x) - f_2(x) \right] \log \frac{f_1(x)}{f_2(x)} dx$$

Bhattacharyya distance:

$$d_B(f_1, f_2) = \ln \left[ \int_{-\infty}^{\infty} f_1^{\frac{1}{2}}(x) f_2^{\frac{1}{2}}(x) dx \right]^{-1}$$

The Bhattacharyya distance is well known to be an upper bound to the probability of erratic decision between $f_1$ and $f_2$. Also, the variational distance in addition to being over sensitive to density changes, it is also very demanding. A more detailed comparative evaluation of the six distances covered in this preliminary discussion is presented in the following section.

3. **Comparative evaluation**

The relationship between Prokhorov and Vasershtein distances has been already given by (3). The following lemma describes a simple relationship between the Lévy, Kolmogorov, and variational distances, where multidimensional distributions are in general considered.
Lemma 1

For $Q_1, Q_2$ multidimensional cumulative distributions and $f_1, f_2$ their corresponding densities, the following ranking is true:

$$d_L(Q_1, Q_2) \leq d_K(Q_1, Q_2) \leq d_{VR}(f_1, f_2) \tag{9}$$

Proof:

1. For the relationship between Lévy and Kolmogorov distances, let

$$d_K(Q_1, Q_2) = \sup_X |Q_1(X) - Q_2(X)| .$$

Then,

$$Q_1(X) - Q_2(X) \leq |Q_1(X) - Q_2(X)| \leq \delta \leq Q_1(\cup Y: \rho(X, Y) \leq \delta) - Q_2(X) + \delta, \forall X$$

and

$$Q_2(X) - Q_1(X) \leq |Q_2(X) - Q_1(X)| \leq \delta \leq Q_1(\cup Y: \rho(X, Y) \leq \delta) - Q_1(X) + \delta, \forall X$$

or

$$\begin{cases} Q_1(X) \leq Q_2(\cup Y: \rho(X, Y) \leq \delta) + \delta, \forall X \\ Q_2(X) \leq Q_1(\cup Y: \rho(X, Y) \leq \delta) + \delta, \forall X \end{cases}$$

Therefore, $\delta$ is a candidate for $d_L(Q_1, Q_2)$ and $d_L(Q_1, Q_2) \leq \delta = d_K(Q_1, Q_2)$.

2. For the relationship between variational and Kolmogorov distances:

$$|Q_1(X) - Q_2(X)| = \left| \int_{-\infty}^{X} \left[ f_1(Y) - f_2(Y) \right] dY \right| \leq$$

$$\leq \int_{-\infty}^{X} |f_1(Y) - f_2(Y)| dY \leq \int_{-\infty}^{\rho} |f_1(Y) - f_2(Y)| dY \leq \sup_X |Q_1(X) - Q_2(X)| \leq d_{VR}(f_1, f_2)$$

It can be seen from the above lemma that the Lévy distance is the weakest, the variational is the strongest and the Kolmogorov lies in between.
The Bhattacharyya and I-divergence distances consist a separate group that is not directly comparable to the previously mentioned distances. In addition, as explained by Kailath [8], the Bhattacharyya and I-divergence distances are not directly comparable either.

At this point it is interesting to make the peripheral comment that the nonsymmetric I-divergence distance given by the expression

$$d_I(f_1, f_2) = \int f_1(Y) \log \frac{f_1(Y)}{f_2(Y)} dY$$

(10)
is also the discrimination or relative entropy of $f_2$ with respect to $f_1$, defined by Wyner [19] for a two-receiver broadcast channel. The symmetric I-divergence distance in (7) can then be looked at as the mutual relative entropy between the two receivers of the same channel. Continuing on the comparative evaluations of the distances, we will present two lemmas involving the Prokhorov, generalized Kolmogorov and Vasershtein distances. The conclusion from these two lemmas is that for particular choices of penalty or distortion measures $\rho(\ldots)$ both the Prokhorov and Vasershtein distances degenerate to the Kolmogorov one.

**Lemma 2**

Let $(\Omega, \mathcal{G}, \mu_1)$ and $(\Omega, \mathcal{G}, \mu_2)$ be two measure spaces with measures such that:

$$\mu_1(\Omega) = \mu_2(\Omega) = S, 0 < \mu_1(A) \leq \mu_1(B); \forall A, B \in \mathcal{G}; i = 1, 2$$

where $S$ some real number.

Let also

$$\rho(A, B) = \begin{cases} S, A \equiv B \\ 0, A \nRightarrow B \end{cases}$$

Then

$$d_{\rho, p}(\mu_1, \mu_2) = d_{K}(\mu_1, \mu_2)$$
Lemma 3

For measure spaces, distortion measure \( \rho(\ldots) \) as in lemma 2, and \( S = 1 \), it is also true that

\[
d_{\mathcal{V}, \rho}(\mu_1, \mu_2) = d_{\mathcal{K}}(\mu_1, \mu_2)
\]

The result expressed by lemma 3 was first found by Dobrushin [13]. An alternative proof for this lemma and proof of lemma 2 are presented in appendix A.

Another property of the distances that is valuable for any optimization problem involving them is convexity. It is easy to show that the variational, Kolmogorov and I-divergence distances are convex \( \cup \) on closed linear manifolds of any of the two distributions involved.

The Vasershtein distance for distributions and the Levy distance are considered interesting cases here and are examined in detail.

Let us first consider the Vasershtein distance for distributions, and denote \( Q_1(X_n), Q_2(Y_n) \) two \( n \)-dimensional distributions at \( X_n \) and \( Y_n \) respectively. In addition, denote by \( R_{Q_1, Q_2}(X_n, Y_n) \) any \( 2n \)-dimensional distribution with \( Q_1, Q_2 \) marginals. For such distributions the Vasershtein distance is given by the following expression:

\[
d_{\mathcal{V}, \rho}(Q_1, Q_2) = \inf \mathbb{E}_{R_{Q_1, Q_2}}[\rho(X_n, Y_n)]
\]

(11)

The following lemma can then be stated.

Lemma 4

For distortion measure \( \rho(\ldots) \neq 0 \), the Vasershtein distance \( d_{\mathcal{V}, \rho}(Q_1, Q_2) \) in (11) is convex \( \cup \) on any closed linear manifold of either \( Q_1 \), or \( Q_2 \).
Proof

Let $\mathcal{B}_{ij}$ be the space of all joint distributions $R(\cdot, \cdot)$ that have $Q_i^1, Q_j^1$ marginals. Consider the $\mathcal{B}_{12}, \mathcal{B}_{13}$ spaces and let $R_1(\cdot, \cdot) \in \mathcal{B}_{12}$, $R_2(\cdot, \cdot) \in \mathcal{B}_{13}$. Then, for every $h \in [0,1]$, the distribution

$$R(\cdot, \cdot) = hR_1(\cdot, \cdot) + (1-h)R_2(\cdot, \cdot)$$

has marginals $Q_1^1$ and $hQ_2^1+(1-h)Q_3^1$. Therefore, for every $R_1(\cdot, \cdot) \in \mathcal{B}_{12}$, $h \in [0,1]$, $R_2(\cdot, \cdot) \in \mathcal{B}_{13}$, the distribution

$$R(\cdot, \cdot) = hR_1(\cdot, \cdot) + (1-h)R_2(\cdot, \cdot)$$

is a member of the space $\mathcal{B}_{1h23}$ that has $Q_1^1, hQ_2^1+(1-h)Q_3^1$ marginals. In other words, the distributions expressed by (12) consist a subspace of the space $\mathcal{B}_{1h23}$.

Therefore,

$$d_{\rho}(Q_1^1, hQ_2^1+(1-h)Q_3^1) = \inf_{R(\cdot, \cdot) \in \mathcal{B}_{1h23}} E_{R(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)]$$

$$\leq \inf_{R(\cdot, \cdot) \in \mathcal{B}_{1h23}} E_{R(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)] = \inf_{R_1(\cdot, \cdot) \in \mathcal{B}_{12}} E_{R_1(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)] + (1-h) \inf_{R_2(\cdot, \cdot) \in \mathcal{B}_{13}} E_{R_2(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)]$$

$$= \inf \left[ h \inf_{R_1(\cdot, \cdot) \in \mathcal{B}_{12}} E_{R_1(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)] + (1-h) \inf_{R_2(\cdot, \cdot) \in \mathcal{B}_{13}} E_{R_2(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)] \right]$$

But since $\rho(\cdot, \cdot) \geq 0$, we can write from above:

$$d_{\rho}(Q_1^1, hQ_2^1+(1-h)Q_3^1) = h \inf_{R_1(\cdot, \cdot) \in \mathcal{B}_{12}} E_{R_1(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)] + (1-h) \inf_{R_2(\cdot, \cdot) \in \mathcal{B}_{13}} E_{R_2(\cdot, \cdot)}[\rho(X_n^n, Y_n^n)]$$

$$= hd_{\rho}(Q_1^1, Q_2^1) + (1-h)d_{\rho}(Q_1^1, Q_3^1)$$

and the proof is here complete, since symmetric analysis leads to similar result for the other distributions involved in the Vasserstein distance.
We should make here the additional observation that the result of the above lemma can be extended to arbitrary measures \( \mu_1, \mu_2 \) and \( \rho(\ldots) \geq 0 \).

Also, we will emphasize here that if the distortion measure \( \rho(\xi_n, \xi_n) \) is symmetric with respect to \( \xi_n \) and \( \xi_n \), the Vaserstein distance is also symmetric with respect to the distributions \( Q_1, Q_2 \). That is, \( d_{\rho}(Q_1, Q_2) = d_{\rho}(Q_2, Q_1) \) then.

At the study of the Lévy distance for convexity, it became evident that such property is secured only if the distance is redefined on a closed internal of the distribution domain. The reason that such redefinition is necessary is that convexity of the underline distributions is required then, and such convexity is not true on the whole \((\infty, \infty)\) for nontrivial such distributions. That will be clear in the following detailed discussion.

To make the discussion as meaningful as possible we will restrict ourselves to one-dimensional distributions \( F \). The arguments and the results can be easily extended to multidimensional spaces.

Let us consider two constants \( a, b \) such that \( a < b \) and define the Lévy distance in the following way:

\[
d_{L, \rho}(F_1, F_2) = \inf \left\{ \varepsilon : F_2(\min(x: \rho(x, y) \leq \varepsilon) - \varepsilon \leq F_1(x) \leq F_2(\max(x: \rho(x, y) \leq \varepsilon) + \varepsilon) ; \forall x \in [a, b] \right\}
\]

(13)

What is implied in the definition (13) is that the domain of interest is \([a, b]\), which means that the values of \( F_1, F_2 \) in the remaining domain are either kept fixed or they have no influence on the system under consideration.

Now, we can present the following lemma:

**Lemma 5**

The Lévy distance expressed by (13) is convex \( \cup \) on the closed linear manifold of distributions \( F_1, F_2 \) that are convex \( \cap \) on \([a-1, b+1] \).
Proof:

We will prove the lemma for $F_2$ only. Due to symmetry the proof for $F_1$ will be the same.

Let $F_1, F_{21}, F_{22}$ be three distributions that are $\cap$ convex on $[a,b]$, and form the distribution $F_2 = hF_{12} + (1-h)F_{22}$, where $0 < h < 1$. The distribution $F_{123}$ is also convex $\cap$ on $[a,b]$. We can write as discussed in [21]:

\[
d_{L,P}(F_1, F_{21}) = \inf \{ \epsilon : F_{21}(x) \left[ F_1(\max(y : \rho(x,y) \leq \epsilon)) + \epsilon \right] \leq 0; \\
F_{21}(x) - \left[ F_1(\min(y : \rho(x,y) \leq \epsilon)) - \epsilon \right] \geq 0; \forall x \in [0,b] \} = \epsilon_1
\]

\[
d_{L,P}(F_1, F_{22}) = \inf \{ \epsilon : F_{22}(x) \left[ F_1(\max(y : \rho(x,y) \leq \epsilon)) + \epsilon \right] \leq 0; \\
F_{22}(x) - \left[ F_1(\min(y : \rho(x,y) \leq \epsilon)) - \epsilon \right] \geq 0; \forall x \in [a,b] \} = \epsilon_2
\] (14)

\[
d_{L,P}(F_1, F_2) = \inf \{ \epsilon : hF_{21}(x) - \left[ F_1(\max(y : \rho(x,y) \leq \epsilon)) + \epsilon \right] + (1-h)F_{22}(x) - \left[ F_1(\max(y : \rho(x,y) \leq \epsilon)) + \epsilon \right] \leq 0; \\
F_{22}(x) - \left[ F_1(\min(y : \rho(x,y) \leq \epsilon)) - \epsilon \right] \geq 0; \forall x \in [a,b] \} = \epsilon_3
\] (15)

Since $d_{L,P}(F_1, F_{21}) = \epsilon_1$, for every $\delta > 0$ there is some $\epsilon_1 \in [a]$, $\epsilon_1 < \delta_1$ that satisfies:

\[
\begin{align*}
\left\{ \begin{array}{l}
F_{21}(x) - \left[ F_1(\max(y : \rho(x,y) \leq \epsilon_1)) + \epsilon_1 \right] \leq 0 \\
F_{21}(x) - \left[ F_1(\min(y : \rho(x,y) \leq \epsilon_1)) - \epsilon_1 \right] \geq 0
\end{array} \right\} \forall x \in [a,b]
\] (16)

Similarly, from $d_{L,P}(F_1, F_{22})$ we obtain that for every $\delta > 0$ there is some
\( \epsilon_{\delta_2} : \epsilon_{\epsilon} \leq \epsilon_{\delta_2} < \epsilon_{\epsilon} + \delta \) that satisfies:

\[
\begin{cases}
F_{22}(x) \left[ F_1(\max(y: \rho(x, y) \leq \epsilon_{\delta_2}) + \epsilon_{\delta_2}) \right] < 0 \\
\forall x \in [a, b]
\end{cases}
\]

\[
F_{22}(x) \left[ F_1(\min(y: \rho(x, y) \leq \epsilon_{\delta_2}))-\epsilon_{\delta_2} \right] > 0
\]

From (16) and (17) it is implied that:

\[
h \left[ F_{21}(x) - \left[ F_1(\max(y: \rho(x, y) \leq \epsilon_{\delta_1})) + \epsilon_{\delta_1} \right] \right] + (1-h) \left[ F_{22}(x) - \left[ F_1(\max(y: \rho(x, y) \leq \epsilon_{\delta_2})) + \epsilon_{\delta_2} \right] \right] < 0
\]

\[
\forall x \in [a, b]
\]

\[
h \left[ F_{21}(x) - \left[ F_1(\min(y: \rho(x, y) \leq \epsilon_{\delta_1})) - \epsilon_{\delta_1} \right] \right] + (1-h) \left[ F_{22}(x) - \left[ F_1(\min(y: \rho(x, y) \leq \epsilon_{\delta_2})) - \epsilon_{\delta_2} \right] \right] > 0
\]

or that:

\[
h F_{21}(x) + (1-h) F_{22}(x) \leq h F_1(\max(y: \rho(x, y) \leq \epsilon_{\delta_1})) + (1-h) F_1(\max(y: \rho(x, y) \leq \epsilon_{\delta_2})) + \left[ h \epsilon_{\delta_1} + (1-h) \epsilon_{\delta_2} \right]
\]

\[
\forall x \in [a, b]
\]

\[
h F_{21}(x) + (1-h) F_{22}(x) \geq h F_1(\min(y: \rho(x, y) \leq \epsilon_{\delta_1})) + (1-h) F_1(\min(y: \rho(x, y) \leq \epsilon_{\delta_2})) - \left[ h \epsilon_{\delta_1} + (1-h) \epsilon_{\delta_2} \right]
\]

Due to the \( \cap \) convexity of \( F_1 \) on \([a-1, b+1]\) we have:

\[
F_1(h \max(y: \rho(x, y) \leq \epsilon_{\delta_1}) + (1-h) \max(y: \rho'(x, y) \leq \epsilon_{\delta_2})) = F_1(x + h \rho^{-1}(\epsilon_{\delta_1}) + (1-h) \rho^{-1}(\epsilon_{\delta_2}))
\]

\[
\geq h F_1(x + \rho^{-1}(\epsilon_{\delta_1})) + (1-h) F_1(x + \rho^{-1}(\epsilon_{\delta_2}))
\]

where \( \rho^{-1}(\epsilon) = \max(y: \rho(x, y) \leq \epsilon) - x \)

Substituting (20) in the first part of (19) we obtain:

\[
h F_{21}(x) + (1-h) F_{22}(x) \leq F_1(x + h \rho^{-1}(\epsilon_{\delta_1}) + (1-h) \rho^{-1}(\epsilon_{\delta_2})) + \xi_{\delta_1} + (1-h) \epsilon_{\delta_2}
\]

\[
\forall x \in [a, b]
\]
The second part of (19) can be treated the same way as discussed in [21]. If \( \rho^{-1}(x) \leq \varepsilon \) it is directly then derived from (21) that

\[
d_L, \rho (F, hF_{21} + (1-h)F_{22}) \leq \delta \varepsilon_1 + \delta (1-h) \varepsilon_2 + \delta (1-h) \varepsilon_2; \forall \varepsilon > 0, \rho(x, y) = |x-y|
\]

Therefore, \( d_L, \rho (F, hF_{21} + (1-h)F_{22}) \leq \varepsilon d_L, \rho (F, F_{21}) + (1-h) d_L, \rho (F, F_{22}) \) and the proof is complete.

We can observe here that a distribution \( F(x) \) that is convex \( \cap \) on \([a-1, b+1]\) is a distribution with negative second derivative in \([a-1, b+1]\) which corresponds to density monotonically decreasing on the same interval.

As a conclusion from lemma 5 we can observe that due to the convexity expressed there, given any distribution \( F \) there is a unique best approximation of it in the Lévy distance sense given by (12), where the approximation is taken from the linear manifold of distributions that are convex \( \cap \) inside a certain closed interval \([a-1, b+1]\).

As we see in the following section, the convexity of the distances besides being valuable for best approximation problems, it is also useful in the search for optimal linear data transformations under restrictions.

4. The distances and data linear transformations

Let \((\Omega, \mathcal{G})\) be a space with a \(\sigma\)-algebra defined on it, and let \( T \) be a transformation on the \(\omega\) elements of the space \(\Omega\). The transformed space will be called \(T\Omega\), and the transformed \(\sigma\)-algebra will be denoted \(T\mathcal{G}\).

**Corollary 1**

\(T\mathcal{G}\) is a \(\sigma\)-algebra if \(\Omega\) is a countable space.
Proof

Let $A, B \in \mathcal{G}$ and denote by $TA, TB$ the transformed sets. Then $TA \cup TB$ and $TA \cap TB$ are obviously equal to $TA \cup B$ and $TA \cap B$ correspondingly. But, $A, B, A \cup B, A \cap B \in \mathcal{G}$. Therefore, $TA, TB, TA \cup B, TA \cap B \in \mathcal{G}$. The same is easily extended to $\bigcup_{i=1}^{n} TA_i$ and $\lim_{n \to \infty} \bigcup_{i=1}^{n} TA_i$.

We want to point out here that if $\Omega$ is not countable the statement of the corollary is not necessarily true. Also, if $\Omega$ is countable so is $T\Omega$, while $T$ is not necessarily a one-to-one transformation.

Now, suppose that a measure space $(\Omega, \mathcal{G}, \mu)$ and a closed convex family $\mathcal{F}$ of transformations $T$ are given, such that for every $T \in \mathcal{F}$, $T\Omega$ is a $\sigma$-algebra. Then, each $T \in \mathcal{F}$ induces a unique measure space $(T\Omega, T\mathcal{G}, \nu_T(\mu))$.

Let two different measures $\mu_1, \mu_2$ assigned as $(\Omega, \mathcal{G})$ and let $T$ be some transformation from the family $\mathcal{F}$. Then, two measures $\nu_T(\mu_1)$ and $\nu_T(\mu_2)$ defined on $(T\Omega, T\mathcal{G})$ are induced by $T, \mu_1, \mu_2$. If some distance $d(\nu_T(\mu_1), \nu_T(\mu_2))$ is convex with respect to $T$ for $T \in \mathcal{F}$, then there is a unique transformation $T_0 \in \mathcal{F}$ that applied on the measure spaces $(\Omega, \mathcal{G}, \mu_1), (\Omega, \mathcal{G}, \mu_2)$ induces measures $\nu_{T_0}(\mu_1), \nu_{T_0}(\mu_2)$ that realize the $\max_{T \in \mathcal{F}} d(\nu_T(\mu_1), \nu_T(\mu_2))$.

In this section we will be concerned with a particular space $(\Omega, \mathcal{G})$, and particular measures $\mu_1, \mu_2$ and transformation $T$. Specifically, $\Omega$ will be the $E^n$ Euclidean space and the $\sigma$-algebra $\mathcal{G}$ will include all sets $(-\infty, x_n]$ where $x_n$ an $n$-dimensional vector defined on $E^n$. The family $\mathcal{G}$ of transformations will be the family of row vectors $G_n$ of dimensionality $n$ that satisfy some restriction. If this restriction is $G_n \leq \alpha \cdot R_n$, where $\alpha$ some constant, and $R$ some $n \times n$ nonnegative matrix, the family of transformations is convex. The measures $\mu_1, \mu_2$ will be, in general, pro-
bability measures, and more specifically Gaussian probability measures defined on \((\mathbb{E}^n_G)\).

Let

\[
\mu_i(\infty, X_n) = \int_{-\infty}^{\infty} f_{n_i}(Y_n) \, dY_n; \quad i=1,2
\]

(22)

where

\[
f_{n_i}(Y_n) = (2\pi)^{-\frac{n}{2}} \exp \left\{ -\frac{1}{2} \left( Y_n - M_{n_i} \right)^T R_{n_i}^{-1} (Y_n - M_{n_i}) \right\}; \quad i=1,2
\]

(23)

Then, for \(T=C_n\) we obtain from (22), (23):

\[
\nu_T(\mu_i)(\infty, Z) = \int_{-\infty}^{\infty} f_{iT}(w) \, dw; \quad i=1,2
\]

(24)

where

\[
f_{iT}(w) = (2\pi)^{-\frac{n}{2}} \left[ \begin{array}{c} C_{n_i} R_{n} C'_{n} \\ \frac{1}{2} \end{array} \right]^{-\frac{1}{2}} \exp \left\{ -\frac{1}{2} \left( \frac{w - C_{n_i} M_{n_i}}{C_{n_i} R_{n} C'_{n}} \right)^2 \right\}; \quad i=1,2
\]

(25)

Finally, let the convex family of transformations \(\mathcal{F}\) be expressed by the restriction

\[
C_{n_i} R_{n} C'_{n_i} \leq A_{n_i n_i} \cdot n_i
\]

(26)

where \(R_{n_i}\) the positive definite covariance matrix in (23) corresponding to \(i=1\).

The optimal transformation \(C_{n_i}\) (if any) that has the best discriminant effects will be sought, where this effect is measured by the Bhattacharyya, I-divergence, Lévy, Vasershtein, Kolmogorov and variational distances. Each of the distances will be examined separately, for the two cases of \(M_{n_1}=M_{n_2}, R_{n_1}=R_{n_2}\).

I. Bhattacharyya distance

In this case, the Bhattacharyya distance in (8) becomes:

\[
d_B(f_{1T}, f_{2D}) = \frac{1}{2} \ln \left( \frac{1}{2} \left( \frac{C_{n_i} R_{n_i} C'_{n_i}}{C_{n_i} R_{n_2} C'_{n_2}} \right) + \frac{1}{2} \left( \frac{C_{n_i} R_{n_2} C'_{n_2}}{C_{n_i} R_{n_1} C'_{n_1}} \right) \right)
\]

(27)
Let \( R_{n1} = W W' \); where \( W \) the matrix of the relative eigenvectors and \( R_{n2} = W W' \);
where \( L \) the diagonal matrix with the eigenvalues \( \lambda_j \) of \( R_{n2} \) w.r.t. \( R_{n1} \). Then, the optimal transformation \( C_n \) that maximizes \( d_B(f_{1T}, f_{2T}) \) under the restriction in (26) is actually a set of infinite values lying on a line and described by:

\[
C_n^o = K \max^{-1}(\lambda_{\text{max}} + \lambda_{\text{max}}^{-1}, \lambda_{\text{min}} + \lambda_{\text{min}}^{-1})
\]  

(28)

where \( K \) any constant that does not exceed absolutely \( \sqrt{A} \).

\[
\max^{-1}(\lambda_{\text{max}} + \lambda_{\text{max}}^{-1}, \lambda_{\text{min}} + \lambda_{\text{min}}^{-1}) = \text{this } C_n \text{ from } \lambda_{\text{min}}, \lambda_{\text{max}} \text{ that realizes the maximum between } \lambda_{\text{max}} + \lambda_{\text{max}}^{-1}, \lambda_{\text{min}} + \lambda_{\text{min}}^{-1}
\]

and \( \lambda_{\text{min}} = [0, 0010.0] W^{-1} \)  

(29)

position corresponding to the minimum \( L \) eigenvalue

\( \lambda_{\text{max}} = [0, 0010.0] W^{-1} \)  

(30)

position corresponding to the maximum \( -eigenvalue \) in \( L \)

The proof of this result is in appendix B.

The maximum distance is given by the following expression:

\[
d_{B_{\text{max}}} = -2 \cdot \ln 2 + \frac{1}{2} \ln \max(\lambda_{\text{max}} + \lambda_{\text{max}}^{-1}, \lambda_{\text{min}} + \lambda_{\text{min}}^{-1})
\]  

(31)

II. Variational distance

\[
d_{V_{r}}(f_{1T}, f_{2T}) = \left| \begin{array}{c}
2 \ln \frac{C_{R_{n1}, C_{n1}}}{C_{R_{n2}, C_{n2}}} + \frac{1}{2} \ln \left( \frac{C_{R_{n1}, C_{n1}}}{C_{R_{n2}, C_{n2}}} \right)^2 - 1 \\
 \frac{1}{2} \ln \left( \frac{C_{R_{n1}, C_{n1}}}{C_{R_{n2}, C_{n2}}} \right)^2 - 1
\end{array} \right|
\]  

(32)
where \( \phi(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp \left\{ -\frac{u^2}{2} \right\} du \)

as shown in appendix B. Again the maximum distance corresponds to

\[
\frac{C_{n} R n^2 C'}{C_{n} R n^2 C'} = \max (\lambda_{\text{max}}, \lambda_{\text{min}}) - 1
\]

where \( \lambda_{\text{max}}, \lambda_{\text{min}} \) the maximum and minimum eigenvalues in \( L \) correspondingly. The corresponding linear "optimal" transformations are again given by (29) and (30) multiplied by any constant not exceeding \( \sqrt{A} \).

The maximum value of the distance is:

\[
d_{V_{\text{rmax}}} = \max \left( \left| \phi\left( \left( \frac{2\ln \lambda_{\text{max}}}{\lambda_{\text{max}}} \right) - \phi\left( \frac{2\ln \lambda_{\text{max}}}{\lambda_{\text{max}}} - 1 \right) \right) \right|
\]

\[
, \left| \phi\left( \left( \frac{2\ln \lambda_{\text{min}}}{\lambda_{\text{min}}} \right) - \phi\left( \frac{2\ln \lambda_{\text{min}}}{\lambda_{\text{min}}} - 1 \right) \right) \right|
\]

(34)

III. Kolmogorov distance

It can be found easily that

\[
d_{K}(f_{1T}, f_{2T}) = \left| \phi\left( \frac{C_{n} R n^2 C'}{C_{n} R n^2 C'} \right) - \phi\left( \frac{C_{n} R n^2 C'}{C_{n} R n^2 C'} - 1 \right) \right|
\]

(35)

The same transformations \( C_{n} \lambda_{\text{min}}, C_{n} \lambda_{\text{max}} \) in (29), (30), (28) stand and

\[
d_{K_{\text{max}}} = \frac{1}{4} d_{V_{\text{rmax}}}
\]

(36)

where \( d_{V_{\text{rmax}}} \) is given by (34)
IV. I-divergence distance

It can easily be found that:

$$d_1(f_{1T}, f_{2T}) = -\frac{1}{2} + \frac{1}{4} \left[ \frac{C_{nR)n_2C'n}}{C_{nR)n_1C'n}} + \frac{C_{nR)n_1C'n}}{C_{nR)n_2C'n}} \right]$$

(37)

It is obvious that in (37) the same symmetries that appear in (27) exist.

Therefore, the "optimal" linear transformation is the same with the one in the Bhattacharyya distance. The maximum distance value is given by:

$$d_{\text{max}} = -\frac{1}{2} + \frac{1}{4} \max \left( \lambda_{\text{max}}^{-1}, \lambda_{\text{min}}^{-1} \right)$$

(38)

V. Le\'vy distance

We feel the Le\'vy and Vasershtein distances last because they both involve a penalty or distortion measure and therefore consist a separate group.

If $p(\cdot, \cdot)$ is the distortion measure used; denote by $p^{-1}(\epsilon)$ the maximum $y$ that gives $p(x, x+y) = \epsilon$ for any $x$. Then, the Le\'vy distance for the equal mean model considered here is given by:

$$d_L, p(f_{1T}, f_{2T}) = \ln \left\{ \epsilon ; \frac{C_{nR)n_1C'n}}{C_{nR)n_2C'n}} + \frac{p^{-1}(\epsilon)}{C_{nR)n_2C'n}} \right\} \leq \epsilon ; \frac{C_{nR)n_1C'n}}{C_{nR)n_2C'n}} \right\} \leq \epsilon ; \frac{C_{nR)n_1C'n}}{C_{nR)n_2C'n}} \right\}$$

(39)

As shown in appendix B, finding the Le\'vy distance for given $C_n$ transformations or even more finding the "optimal" discriminant transformation in this case becomes a task that can be only approached numerically. This is a strong indication of the fact that the Prokhorov and Le\'vy distances are characterized by the disadvantage of difficult calculability. In cases that the inclusion of a penalty or distortion measure is desirable, the Vasershtein distance is a better choice as we will show below.

VI. Vasershtein distance

We will work with specific distortion measures here. The first such distortion measure to be examined will be the popular $p_B(x, y) = (x-y)^2$. 
For the equal mean case we are considering here, it can be shown directly:

\[
d_{V,P}(f_{1T}, f_{2T}) = \inf \{ \mathcal{C}_n R_{n1} C'_n + \mathcal{C}_n R_{n2} C'_n - 2E\{y_n C_{n1} (x_n C_{n2})\} \}
\]

(40)

As shown in [16] the Vaserstein distance \( d_{V,P}(f_{1T}, f_{2T}) \) can be actually found if the knowledge of some structure involving the intial data \( X_n, Y_n \) is assumed.

Specifically, let \( X_n \) be \( n \) samples from or Gaussian, wide sense stationary process whose nth order statistics are described by \( f_{n1}(X_n) \) in (23). Then, the auto-correlations matrix \( R_{n1} \) is a Toeplitz matrix. Let \( Y_n \) be from a Gaussian wide sense stationary process also whose nth order statistics are described by \( f_{n2}(Y_n) \) in (23) and \( R_{n2} \) is again Toeplitz. Then the scalar variables \( C_{X_n}, C_{Y_n} \) are samples from Gaussian, wide sense stationary processes also. In fact, the power spectra of the variables \( C_{X_n}, C_{Y_n} \) exist and are given by the following expressions correspondingly:

\[
\mathcal{P}(\lambda) = \sum_{k=-\infty}^{\infty} C_{n1} R_{n1}(k) C'_n e^{ik\lambda}
\]

(41)

\[
\mathcal{P}(\lambda) = \sum_{k=-\infty}^{\infty} C_{n2} R_{n2}(k) C'_n e^{ik\lambda}
\]

(42)

where \( \mathcal{P}(\lambda); i=1,2 \) denotes power spectrum under corresponding order statistics in \( f_{iT}, f_{iT_n} \) transformation. Also, \( R_{n1}(k) = E\{(X_{n+M_n1}) (X_{n+k-M_n1})'\} \), where the expectation is taken over the statistics that in order are given by \( f_{ni} \) in (23), and what has been denoted by \( R_{ni}(o) \) till now is actually \( R_{ni}(o) \).

Let us restrict ourselves to cross-stationary processes. Then the infimum in (40) will be taken over all cross-stationary statistics with \( f_{IT}, f_{2T} \) marginals, and the cross power spectrum exists and is denoted by \( \mathcal{P}(\lambda) \).

\[
\mathcal{P}(\lambda) = \sum_{k=-\infty}^{\infty} \mathcal{C}_n R_{n1}(k) C'_n e^{ik\lambda}
\]

As explained in [16] p. 324, the Vaserstein distance under the above restrictions is given by the following expression:
\[ d_{\Psi} \rho_g(f_{1T}, f_{2T}) = (2\pi)^{-\frac{1}{2}} \int_{-\pi}^{\pi} \left| \rho^{\lambda}_{f_{1T}, f_{2T}}(\lambda) - \rho^{\lambda}_{f_{1T}, f_{2T}}(\lambda) \right|^2 d\lambda \]  

where \( \rho_{f_{1T}}(\lambda) \) are given by (41) and (42). We want to point out here that for the existence of \( \rho_{f_{1T}}(\lambda) \) it is sufficient that the vectors \( X_n, Y_n \) form cross stationary processes in time. In this case, the matrices \( R(0), R(1) \) do not have to be Toeplitz.

Let \( X_n(j), Y_n(j) \) denote \( n \)-dimensional data, collected at time \( j \) from populations distributed as \( X_n, Y_n \) correspondingly. Let both \( X_n(j), Y_n(j) ; j = 0, 1, \ldots \) be first order Markov. Then, the spectra in (41) and (42) become:

\[ \rho_{f_{1T}}(\lambda) = C R_{n1}^{(0)}(\lambda) C_{n1}^{(1)} \cos \lambda \]

\[ \rho_{f_{2T}}(\lambda) = C R_{n2}^{(0)}(\lambda) C_{n2}^{(1)} \cos \lambda \]

If expressions (44) and (45) are substituted in (43) the following expression is obtained:

\[ d_{\Psi} \rho_g(f_{1T}, f_{2T}) = C \left[ R_{n1}(\lambda) + R_{n2}(\lambda) \right] C_{n1}^{(1)} \cos \lambda \]

\[ \int_{-\pi}^{\pi} \left| \left[ C R_{n1}^{(0)}(\lambda) C_{n1}^{(1)} - C R_{n2}^{(0)}(\lambda) C_{n2}^{(1)} \right] \left. \rho^{\lambda}_{f_{1T}, f_{2T}}(\lambda) \right|^2 d\lambda \]  

Calculating the expression in (46) analytically to study extremes with respect to the linear transformation \( C_n \) is not possible. For that reason we are using bounds. Indeed, applying the Schwartz inequality on the integral in (46) we obtain:

\[ d_{\Psi} \rho_g(f_{1T}, f_{2T}) \geq \left[ \sqrt{C R_{n1}(0) C_{n1}^{(1)}} - \sqrt{C R_{n2}(0) C_{n2}^{(1)}} \right]^2 \]

with equality if and only if there is some constant \( B \) such that:

\[ C_n \left[ R_{n1}(0) - BR_{n2}(0) \right] + 2 \cos \left[ R_{n1}(1) - BR_{n2}(1) \right] C_{n1}^{(1)} = 0 \]

for almost all \( \lambda \in [-\pi, \pi] \).
To maximize $d_{V, \rho_s}(f_{1T}, f_{2T})$ with respect to the $C_n$ choice we will maximize the lower bound in (47) instead. Since this bound can be written:

$$B(\rho_s) = C_n \left[ 1 - \sqrt{\frac{C_R n_2(o) C'}{C_R n_1(o) C}} \right]^2$$

and due to the fact that, as shown in appendix B, the ratio $\frac{C_R n_2(o) C'}{C_R n_1(o) C}$ can only vary in $[\lambda_{\min}, \lambda_{\max}]$ with $C_n$ changing (where $\lambda_i$ the eigenvalues in $L$), the bound in (49) can increase to infinity for unrestricted $C_n$ transformations. However, if (26) is true the bound in (49) is maximized for:

$$C_n = \sqrt{A} [0...010..0] W^{-1}$$

where the value 1 in $[0...010..0]$ corresponds to this position in $L$ that belongs to $\max (\lambda_{\max}, \lambda_{-1 \min})$. The value of this maximum bound is given by:

$$B(\rho_s) = A \left[ 1 - \max (\lambda_{\max}, \lambda_{-1 \min}) \right]^2$$

We want to emphasize here that the Vasershtein distance as well as the bound in (49) depend only on the second-order statistics of the data $X = \{x, y\}, Y = \{f\}$ and they are totally insensitive to the exact underline distribution. This property is valuable in the case of ill-defined environments.

If the distortion measure is $\rho_L(x, y) = |x-y|$ instead of $(x-y)^2$, the Vasershtein distance $d_{V, \rho_L}(f_{1T}, f_{2T})$ is bounded from below ([16], th. 5) by

$$B(\rho_L) = (2\pi)^{\frac{1}{2}} \left[ C_R n_2(o) C - C_R n_1(o) C' \right]$$

The bound in (52) is obviously maximized for the transformation in (50), where the restriction (26) is again true. This maximum is given by the following expression:
\[ B_{\text{max}}(\rho_{\lambda}) = 2\pi \left( 1 - \max(\lambda^{-1}_{\text{max}}, \lambda^{-1}_{\text{min}}) \right) \]  

(53)

VII. General Observations

It is evident from the preceding analysis that for data \( X_n, Y_n \) distributed as described by \( f_{n1}(X_n), f_{n2}(Y_n) \) in (23) correspondingly with \( M_{n1} = M_{n2} \), and restricted linear transformations \( C_n \), where the restriction is described by (26), the Bhattacharyya, I-divergence, Kolomogorov and variational distances are all maximized by the same transformation

\[ C_n = K[0...010...0]W^{-1} \]  

(54)

where \( R_{n1} = W_{n1} \), \( R_{n2} = W_{n2}L, L = \{\lambda_1\} \) and the digit 1 in (54) corresponds to the position of \( \max(\lambda^{-1}_{\text{max}}, \lambda^{-1}_{\text{min}}) \). The amplitude \( K \) is such that: \( K \in [-\sqrt{A}, \sqrt{A}] \).

The Vasershtein distance with the implication of \( X_n(j), Y_n(j); j=0,1,... \) being \( n \) dimensional stationary, first order Markov processes and with underline distortion measures either \( \rho_\phi(x,y) = (x-y)^2 \) or \( \rho_\phi(x,y) = |x-y| \), does not require the specific statistics described by (23). In addition, a certain lower bound on this distance is maximized again by the transformations \( C_n \) in (54), where the amplitude \( K \) is equal to \( \sqrt{A} \).

b. \( R_{n1} = R_{n2} = R; M = M_{n1} = M_{n2} \)

1. Bhattacharyya distance

The Bhattacharyya distance is given in this case by the following expression:

\[ d_B(f_{1T}, f_{2T}) = \frac{1}{8} \left( \frac{C_{nn} C_{nn}'}{C_{nn} + C_{nn}'} \right)^2 \]  

(55)

Our objective is to maximize the ratio in (55) with respect to linear transformations \( C_n \) that satisfy the restriction in (26).

It is straightforward to obtain the following expression for the "optimal" \( C_n \):
\[ C = K M_n R_n^{-1} \]
\[ K \in [-\sqrt{A}, \sqrt{A}] \]  
(56)

The maximum value of the distance is:
\[ d_B = \frac{1}{2} M_n R_n^{-1} M_n \]
(57)

### 1. Variational distance

It is easy to find that here:
\[ d_{Vr}(f_1, f_2) = 2 \left| \Phi \left( \frac{C M_n}{2 \sqrt{C R_n C_n'}} \right) - \Phi \left( \frac{-C M_n}{2 \sqrt{C R_n C_n'}} \right) \right| \]
(58)

where,
\[ \Phi(x) = \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{u^2}{2}\right) du \]

The distance in (58) is maximized for this \( C_n \) that realizes the maximum
\[ \left| \frac{C M_n}{2 \sqrt{C R_n C_n'}} \right| \]
which is the one in (55) again.

The maximum distance value is given by:
\[ d_{Vr_{\text{max}}} = 2 \left[ \Phi \left( \frac{-2^{1/2} M_n R_n^{-1} M_n}{n n} \right) - \Phi \left( \frac{2^{1/2} M_n R_n^{-1} M_n}{n n} \right) \right] \]
(59)

### 1. Kolmogorov distance

Then,
\[ d_K(f_1, f_2) = \left| \Phi \left( \frac{C M_n}{2 \sqrt{C R_n C_n'}} \right) - \Phi \left( \frac{-C M_n}{2 \sqrt{C R_n C_n'}} \right) \right| \]
(60)

\[ d_{K_{\text{max}}} = 2^{-1} d_{Vr_{\text{max}}} \]
(61)

where \( d_{Vr_{\text{max}}} \) is given by (59) and the "optimal" \( C_n \) is again the one in (56).

### IV. 1-divergence distance

It can be easily found again that in the present case:
\[ d_1(f_1, f_2) = 2^{1/2} \frac{(C M_n)^2}{C R_n C_n'} \]
(62)

and of course the maximum is also obtained by the \( C_n \) in (56) and
\[
d_{\text{max}} = \frac{1}{2} \left( M_n R_n^{-1} M_n \right)
\]

(63)

V. Lévy Distance

As we will see, in this case of equal convariances the "optical" transformation in the Lévy distance sense can be found. It is shown in appendix B that in the present case:

\[
d_{L, \rho} (f_{\text{IT}}, f_{\text{2T}}) = \inf \left\{ \varepsilon : \tilde{\rho} \left( \frac{-1}{2} \left( C_R \frac{C_C'}{n_n n_n} \right) \right) - \tilde{\rho} \left( \frac{C_M}{2} \right) \leq \varepsilon \right\}
\]

(64)

where \( \rho^{-1}(\varepsilon) = \max \left( \gamma : (x, x + y) = \varepsilon \right) \)

For momentarily fixed power \( C_R C'_n \), the transformation that obtains maximum \( d_{L, \rho} \) in (64) is the one that maximizes \( \frac{C_M}{n_n n_n} \). That is because for \( \frac{C_M}{n_n n_n} \) value equal to \( x_1 < x_2 \), it is obviously true that every \( \varepsilon \) candidate for \( d_{L, \rho} (f_{\text{IT}}, f_{\text{2T}}) \) with \( \frac{C_M}{n_n n_n} = x_2 \) instead.

So, letting new \( C_R C'_n \) vary in \([0, A]\), we obtain the maximum Lévy distance in (64) for \( C_n \) as in (56) with \( K \) amplitude fixed and equal to \( \sqrt{A} \).

VI. Vasershtein Distance

Let again (as in VI-1) \( X_n(j), Y_n(j) ; j = 0, \ldots \) be stationary \( n \)-dimensional processes that are also first order Markov. Let \( X_n(j) \) come from a population with \( M_{\text{n1}} \) and \( R_n(0) = R_n(1) \), and let \( Y_n(j) \) come from another population with \( M_{\text{n2}} \) and same \( R_n(0), R_n(1) \). The spectra \( P_{f_{\text{1T}}} (\lambda), P_{f_{\text{1T}}} (\lambda) \) in (42), (43) are then equal and the Vasershtein distance \( d_{f_{\text{1T}}} \) for cross-stationary \( X_n(j), Y_n(j) \) is realized for joint spectrum
\[
\begin{align*}
\mathbf{P}_{\mathbf{f}_{1T} \mathbf{f}_{2T}}^{(\lambda)} &= \left[ \mathbf{P}_{\mathbf{f}_{1T}}^{(\lambda)} \mathbf{P}_{\mathbf{f}_{2T}}^{(\lambda)} \right]^{\frac{1}{2}} \quad \text{and it is equal to:} \\
& \left[ \mathbf{P}_{\mathbf{f}_{1T}}^{(\lambda)} \mathbf{P}_{\mathbf{f}_{2T}}^{(\lambda)} \right]^{\frac{1}{2}}
\end{align*}
\]

where \( \rho_s(x,y) = (x - y)^2 \).

The distance in (65) is obviously maximized for \( C_n \) given by (56) with fixed amplitude \( K = \sqrt{A} \).

The maximum value of the distance is:

\[
d_{V_{\rho_s}}^{\text{max}} = A(M R_n^{-1} M_n)^2
\]

(66)

If the distortion measure is \( \rho_{\mathbf{d}}(x,y) = |x - y| \), then

\[
E(\rho_{\mathbf{d}}(x,y)) = E\left[ |(x - C M_n^{(1)} - (y - C M_n^{(2)}) - C M_n^{(1)}| \right]
\]

(67)

where the expectation is over all joint statistics with \( f_{1T}, f_{2T} \) marginals.

For this case of equal spectra, and due to the lower bound given by theorem 5 in [16], we have from (67):

\[
E(\rho_{\mathbf{d}}(x,y)) \geq |C M_n| - E\left[ |(x - C M_n^{(1)} - (y - C M_n^{(2)})| \right] \geq
\]

\[
\geq |C M_n| - \pi^{-1} \left[ \int_{-\pi}^{\pi} |\mathbf{P}_{\mathbf{f}_{1T}}^{\frac{1}{2}}(\lambda) - \mathbf{P}_{\mathbf{f}_{2T}}^{\frac{1}{2}}(\lambda)| d\lambda \right]^{\frac{1}{2}} =
\]

\[
= |C M_n|
\]

*Foot Note: For the structure considered here and in general \( R_{n1}(k) \neq R_{n2}(k) \); \( k = 0, 1, ..., \) \( M_{n1} \neq M_{n2} \) - the Vaserstein distance is given by the expression:

\[
d_{V_{\rho_s}}(f_{1T}, f_{2T}) = (2\pi)^{-1} \int_{-\pi}^{\pi} |\mathbf{P}_{\mathbf{f}_{1T}}^{\frac{1}{2}}(\lambda) - \mathbf{P}_{\mathbf{f}_{2T}}^{\frac{1}{2}}(\lambda)| d\lambda + (C M_n)^2
\]

(68)
and the rate distortion theory, have been evaluated and used for the linear reduction of Gaussian data to one scalar parameter. It was found that while the Bhattachayya, l-divergence, variational, kalmogorov and Lévy distances are over-sensitive to the underline statistics, the Vasershtein distance depends only on second order moments.

Also, while the Lévy distance is hard to calculate analytically even in the simple case of Gaussian data, simple lower bound on the Vasershtein distance can be found for the distortion measures \( \rho_s(x,y) = (x-y)^2 \)
\( \rho_2(x,y) = |x-y| \).

Finally, for the Gaussian data and the linear reduction mentioned above, it was found that all distances (whenever the result analytically feasible) give the same "optimal" transformation with the most highly class-discrimination properties. This is true in both equal-mean and equal-covariances cases.

20. S. Cambaruis, G. Sinous and W. Strout (1976), "Inequalities for Ek(X,Y) when the Marginals are Fixed," Institute of Statistics mimeo Series no. 1053, University of North Carolina, Chapel Hill.

Appendix A

For the proof of inequality (3) in section 2, the following theorem by Strassen ([7], Th. 11) is needed.

Theorem 1

Given two measures \( \mu_1, \mu_2 \) defined on the separable complete space \((\Omega, \mathcal{A})\), the inequality

\[
\inf \{ \varepsilon : \mu_1(A) \leq \mu_2(UB; B \in \mathcal{A}, \rho(A, B) \leq \varepsilon) + \varepsilon ; \forall A \in \mathcal{A} \} \leq \zeta
\]

\((a_1)\)

is true if and only if there is some joint measure \( r(A, B) \) with \( \mu_1(A), \mu_2(B) \) marginals such that

\[
r(A, B : \rho(A, B) > \zeta) < \zeta \quad \text{(a_2)}
\]

Using Theorem 1 we will prove the following lemma.

Lemma 1

If \( d_{p, \rho}(\mu_1, \mu_2), d_{V, \rho}(\mu_1, \mu_2) \) are the Prokhorov and Vasershtein distances correspondingly as defined by (1) and (2), then for every \( \mathcal{A}(\cdot, \cdot) \) and measures \( \mu_1, \mu_2 \) defined on \((\Omega, \mathcal{A})\) and such that \( \mu_1(\Omega) = \mu_2(\Omega) \) the following inequality is true:

\[
d_{V, \rho}(\mu_1, \mu_2) \geq [d_{p, \rho}(\mu_1, \mu_2)]^2
\]

\((a_3)\)

Proof:

\[
d_{p, \rho}(\mu_1, \mu_2) = \inf \{ \varepsilon : \mu_1(A) \leq \mu_2(UB; B \in \mathcal{A}, \rho(A, B) \leq \varepsilon) + \varepsilon ; \forall A \in \mathcal{A} \} = \varepsilon
\]

For \( \delta > 0 \), there is some \( \varepsilon_\delta \) : \( \varepsilon < \varepsilon_\delta \leq \varepsilon + \delta \) and there is some \( A_0 \) giving:

\[
\mu_1(A_0) \geq \mu_2(UB; B \in \mathcal{A}, \rho(A, B) \leq \varepsilon_\delta) + \varepsilon_\delta
\]
By theorem 1, there is then no joint measure \( r(\cdot, \cdot) \) such that
\[
\begin{align*}
    r(A, B; \rho(A, B) > \varepsilon_0) &< \varepsilon_0.
\end{align*}
\]
That is, for every \( r(\cdot, \cdot) \) choice it is true that
\[
\begin{align*}
    r(A, B; \rho(A, B) > \varepsilon_0) &\leq \varepsilon_0.
\end{align*}
\]
Since
\[
E_r(\rho(A, B)) = E_r(\rho(A, B)) + E_r(\rho(A, B)) \geq A, B: \rho(A, B) > a \quad A, B: \rho(A, B) \leq a
\]
\[
\geq a \ r(A, B; \rho(A, B) > a) \quad \forall a
\]
we can obtain that for every \( r(\cdot, \cdot) \) choice it is true that
\[
E_r(\rho(A, B)) \geq \varepsilon_0 \ r(A, B; \rho(A, B) > \varepsilon_0) \geq \varepsilon_0^2.
\]
Therefore, if by \( \varepsilon_v \) we denote the Vaserstein distance, we have:
\[
\varepsilon_v = \inf \ E_r(\rho(A, B)) \geq \varepsilon_0^2 \geq \varepsilon_p^2.
\]
every \( r(\cdot, \cdot) \) with \( \mu_1, \mu_2 \) marginals.

Proof of Lemma 2.

If \( \rho(A, B) = \{ \begin{align*}
    S &A \neq B \\
    0 &A = B
\end{align*} \), then the inequality:
\[
\mu_1(A) \leq \mu_2(UB; B \in A \setminus \rho(A, B) \leq \varepsilon_0) + \varepsilon
\]
is equivalent to
\[
\begin{align*}
    \mu_1(A) &\leq \mu_2(A) + \varepsilon \quad ; \quad \varepsilon < S
\end{align*}
\]
\[
\begin{align*}
    \mu_1(A) &\leq \mu_2(UB; B \in A \setminus \rho(A, B) \leq \varepsilon_0) + \varepsilon = \mu_2(\Omega) + \varepsilon \quad ; \quad \varepsilon \geq S
\end{align*}
\]
If \( \mu_1(\Omega) = \mu_2(\Omega) \geq \max (\mu_1(A), \mu_2(A)) \quad \forall A \in C \)
then the second part of \( (a_4) \) is always true (for all \( A \in C \)) because
\[
\mu_1(A) \leq \mu_2(UB; B \in A) = \mu_2(\Omega) \quad \forall A \in C.
\]
Thus, the
\[
\inf \{ \varepsilon : \mu_1(A) \leq \mu_2(UB; B \epsilon \Omega, \rho(A, B) \leq \varepsilon) + \varepsilon ; \forall A \in \Omega \} \quad (a_3)
\]
is equal to \( S \) if for every \( \varepsilon < S \) there is some \( A \in \Omega \) such that either
\( \mu_1(A) > \mu_2(A) + \varepsilon \) or \( \mu_2(A) > \mu_1(A) + \varepsilon \).

That is because then:
\[
\sup_{A \in \Omega} | \mu_1(A) - \mu_2(A) | > \varepsilon \quad \forall \varepsilon < S \quad \text{which leads to:}
\]

\[
\sup_{A \in \Omega} | \mu_1(A) - \mu_2(A) | \geq S.
\]
But since \( 0 \leq \mu_1(A) \leq S \); \( \forall A \in \Omega \);
\( i = 1, 2 \), the supremum above cannot exceed \( S \) and it can only be equal to it.

On the other hand, if for some \( \varepsilon < S \), the inequalities \( \mu_1(A) \leq \mu_2(A) + \varepsilon \)
are true \( \forall A \in \Omega \), then the infimum in \((a_3)\) becomes equal to:
\[
\inf_{\varepsilon} \{ \varepsilon : \varepsilon < S, \mu_1(A) \leq \mu_2(A) + \varepsilon \}.
\]

\[
= \inf_{\varepsilon} \{ \varepsilon : \varepsilon < S, | \mu_1(A) - \mu_2(A) | \leq \varepsilon \}.
\]

\[
= \sup_{A \in \Omega} | \mu_1(A) - \mu_2(A) | = d_K(\mu_1, \mu_2)
\]

The proof is now complete.

Proof of Lemma 3

We have in this case:
\[
d_{V, p}(\mu_1, \mu_2) = \inf r(A, B; A, B \in \Omega, A \neq B)
\]
r(\(\cdot, \cdot\)) with \(\mu_1, \mu_2\) marginals

\[
= \inf r(A, B; A, B \in \Omega, \rho(A, B) = 1) =
\]
r(\(\cdot, \cdot\)) w.m. \(\mu_1, \mu_2\)

\[
= \inf r(A, B; A, B \in \Omega, \rho(A, B) \geq 1) \quad (a_6)
\]
r(\(\cdot, \cdot\))

Let \( d_{V, p}(\mu_1, \mu_2) = e_V \leq 1 \).
Then, we obtain from (a_6):

\[ \inf r(A; B; A, B \in \Omega, \rho(A, B) \geq 1) = \epsilon_v \]

\[ r(\cdot, \cdot) \]

So, for every \( \delta > 0 \) there is some \( r(\cdot, \cdot) \) with \( \mu_1, \mu_2 \) marginals such that

\[ r(A; B; A, B \in \Omega, \rho(A, B) \geq 1) < \epsilon_v + \delta \]

From theorem 1 we obtain then:

\[ \mu_1(A) \leq \mu_2(U_B; B \in \Omega, \rho(A, B) \leq \epsilon_v + \delta) + \epsilon_v + \delta \quad \forall \epsilon \in \Omega \quad (a_7) \]

Expression \((a_7)\) is true only for \( \delta > 0 \).

Therefore,

\[ \inf \{ \epsilon : \mu_1(A) \leq \mu_2(U_B; B \in \Omega, \rho(A, B) \leq \epsilon) + \epsilon \quad \forall \epsilon \in \Omega \} = \epsilon_v \quad (a_8) \]

But, as shown in the proof of lemma 2,

\[
\inf \{ \epsilon : \mu_1(A) \leq \mu_2(U_B; B \in \Omega, \rho(A, B) \leq \epsilon) + \epsilon \quad \forall \epsilon \in \Omega \}
= \sup_{A \in \Omega} \frac{\mu_1(A) - \mu_2(A)}{\mu_1(A) + \mu_2(A)} = d_{K}(\mu_1, \mu_2) \quad (a_9)
\]

From \((a_8)\) and \((a_9)\) we conclude that for the measure \( p(A, B) \) as expressed by lemma 3, it is true that:

\[ d_{K}(\mu_1, \mu_2) = d_{K}(\mu_1, \mu_2) \]

Appendix B

Proof of result in 4aI:

\[
\frac{C_n^R n^{-2} C_n^C n^{-1}}{n} \]

Denote \( x = \frac{C_n^R n^{-2} C_n^C n^{-1}}{n} \). Then,

\[
\frac{1}{2} \left( \frac{C_n^R n^{-2} C_n^C}{n^{-1} n} \right) + \frac{1}{2} \left( \frac{C_n^R n^{-1} C_n^C}{n^{-2} n} \right) = \frac{1}{2} x + \frac{1}{2} x - \frac{1}{2} x = g(x) \quad (b_1)
\]

monotonically decreasing from \( x < 1 \) to \( x = 1 \) and monotonically increasing from \( x = 1 \) to \( x > 1 \). Therefore, if there are any restrictions on the value
of \( x \), \( g(x) \) will assume its maximum for either the minimum or the maximum \( x \) allowed. Now, if we define \( D = \{ d_i \} ; i = 1, \ldots, n \) = \( C_{nn} W \), where \( R_{nn} = WW' \), we obtain:

\[
\lambda^{-1} = \frac{C_{nn} R_{nn} C'}{C_{nn} R_{nn} C'} = \sum_{i=1}^{n} \frac{d_i^2}{n \sum_{j=1}^{n} d_j^2}
\]

where \( L = (\lambda_i) ; R_{nn} = WLW' \).

For every \( i, \ o \leq \frac{d_i^2}{\sum_{j=1}^{n} d_j^2} \leq 1 \), \( \lambda_i > o \) and \( \sum_{i=1}^{n} d_i^2 = 1 \)

Therefore, the maximum value \( \lambda^{-1} \) can take is equal to \( \lambda_{\text{max}} \), which is the maximum eigenvalue in \( L \), and this is realized by \( D = [o, \ldots o, k, o, \ldots o] = C_{nn} W \uparrow \)

where \( k \) any constant.

From (b3) we obtain

\[
\lambda_{\text{max}} = k [o, \ldots o,1, o, o] W^{-1}
\]

position of \( \lambda_{\text{max}} \) (b4)

The minimum value \( \lambda^{-1} \) can take is \( \lambda_{\text{min}} \) and is similarly leading to:

\[
\lambda_{\text{min}} = k [o, \ldots o,1, o, o] W^{-1}
\]

position of \( \lambda_{\text{min}} \) (b5)

Applying the restriction \( C_{nn} R_{nn} C' \leq A \) to (b4) and (b5) we obtain: \( |k| \leq \sqrt{A} \).

Proof for 4a

Denote \( x = \frac{C_{nn} R_{nn} C'}{C_{nn} R_{nn} C'} \)

Then

\[
d_{Vr}(f_1, f_2) = 4 \left( \phi \left( \sqrt{\frac{2t_{nx}}{x^2-1}} \right) - \phi \left( \sqrt{\frac{2t_{nx}}{x^2-1}} \right) \right)
\]
For $x \geq 1$
\[
\frac{2\ln x}{x^2 - 1}
\]
is monotonically decreasing from $\infty$ to zero with $x$ increasing
from $x = 1$ to infinity.

Also, $(x - 1)\sqrt{\frac{2\ln x}{x^2 - 1}}$ increases monotonically for $x$ increasing from $x = 1$
to infinity.

Therefore, \[
\frac{2\ln x}{x^2 - 1} - \frac{2\ln x}{x^2 - 1}
\]
is increasing monotonically with
$x$ increasing from $x = 1$ to infinity. Similarly, \[
\frac{2\ln x}{x^2 - 1} - \frac{2\ln x}{x^2 - 1}
\]
is monotonically increasing with $x$ decreasing from $x = 1$ to $-\infty$.

**Proof for 4a)**

Denote $x = \frac{C R_n C'}{n^2 C_n}$; $\sigma_1 = \frac{C_n R_n C'}{C_n}$
and let us consider that $x < 1$. For $x > 1$ symmetric procedure holds.

Then, the Levy distance in (40) becomes:
\[
d_{L, \rho}(f_1, f_2) = \inf \{ \varepsilon : \| f(x) - f(y + \frac{\rho^{-1}(\varepsilon)}{\sigma_1}) \| \leq \varepsilon ; \forall y \}
\]
if the inequality in (b) should be true for every $y$ and for given $\varepsilon, x$,
it is sufficient that it is true for this $y$ that obtains the $g(y) = \frac{1}{\sigma_1}
\frac{\rho^{-1}(\varepsilon)}{\sigma_1}$ maximum. Taking the first derivative of $g(y)$ we find
\[
g'(y) = \frac{1}{x} \varphi(y) - \varphi(y + \frac{\rho^{-1}(\varepsilon)}{\sigma_1})
\]
where $\varphi(u) = \frac{\exp(-\frac{u^2}{2})}{\sqrt{2\pi}}$

The derivative $g'(y)$ is nonnegative for these $y$'s that satisfy:
\[
\ln \frac{1}{x} + \frac{1}{2} \frac{y^2}{x^2} \geq -\frac{1}{2} (y + \frac{\rho^{-1}(\varepsilon)}{\sigma_1})^2
\]
Or for:

\[
\frac{p^{-1}(\varepsilon)}{\sigma_1} - \sqrt{\frac{1}{x^2} \left( \frac{p^{-1}(\varepsilon)}{\sigma_1} \right)^2 + 2 \left( \frac{1}{x^2} - 1 \right) \frac{1}{x} \ln \frac{1}{x}} \leq y \leq \frac{1}{x^2} - 1
\]

\[
\frac{p^{-1}(\varepsilon) + \sqrt{\frac{1}{x^2} \left( \frac{p^{-1}(\varepsilon)}{\sigma_1} \right)^2 + 2 \left( \frac{1}{x^2} - 1 \right) \frac{1}{x} \ln \frac{1}{x}}}{\sigma_1} \leq \frac{1}{x^2} - 1
\]

(b_6)

Due to this and the fact that \( g(-\infty) = 0 \), we see that \( g(g) \) obtains maximum at

\[
y = \frac{\frac{p^{-1}(\varepsilon)}{\sigma_1} + \sqrt{\frac{1}{x^2} \left( \frac{p^{-1}(\varepsilon)}{\sigma_1} \right)^2 + 2 \left( \frac{1}{x^2} - 1 \right) \frac{1}{x} \ln \frac{1}{x}}}{\sigma_1} \leq \frac{1}{x^2} - 1
\]

and for \( x < 1 \) the distance in (b_6) becomes:

\[
d_{L, p}(f_1, f_2) = \inf \left\{ \varepsilon : \frac{p^{-1}(\varepsilon)}{\sigma_1} + \sqrt{\frac{1}{x^2} \left( \frac{p^{-1}(\varepsilon)}{\sigma_1} \right)^2 + 2 \left( \frac{1}{x^2} - 1 \right) \frac{1}{x} \ln \frac{1}{x}} \leq \varepsilon \right\}
\]

(b_9)

If this \( x < 1 \) that makes the distance in (b_9) maximum can be found, the transformation \( C_n \) that obtains this \( x \) can be found also as in the cases of Bhattacharyya, \( l \)-divergence, variational and Kolmogorov distances.

However, the task proves to be such that only numerical methods can approach it.
Proof for 4bV

For the equal covariance case in 4b, the Lévy distance is given by:

$$d_{L, \rho}(f_{1T}, f_{2T}) = \inf \{ \varepsilon : \phi(x) - \phi(x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2} ) \leq \varepsilon \}$$ (b10)

\[ \phi(x + \frac{CM}{n^2 n^2 n^2}) - \phi(x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2}) \leq \varepsilon ; \forall x \}

Denote:

$$g_1(x) = \phi(x) - \phi(x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2})$$ (b11)

$$g_2(x) = \phi(x + \frac{CM}{n^2 n^2 n^2}) - \phi(x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2})$$ (b12)

$$\frac{\partial g_1(x)}{\partial x} = g'_1(x) = \varphi(x) - \varphi(x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2})$$ (b13)

$$\frac{\partial g_2(x)}{\partial x} = g'_2(x) = \varphi(x + \frac{CM}{n^2 n^2 n^2}) - \varphi(x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2})$$ (b14)

$$g'_1(x) \text{ is positive for:}$$

$$\left(2x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2} \right) \left(\frac{CM}{n^2 n^2 n^2} + \frac{CM}{n^2 n^2 n^2} \right) > 0$$ (b15)

$$g'_2(x) \text{ is positive for:}$$

$$\left(2x + \frac{1}{\rho} (\varepsilon) + \frac{CM}{n^2 n^2 n^2} \right) \left(\frac{CM}{n^2 n^2 n^2} - \frac{CM}{n^2 n^2 n^2} \right) > 0$$ (b16)

Let \( \varepsilon_1 \) be a candidate for \( d_{L, \rho}(f_{1T}, f_{2T}) \) in (b10).
Then,

1. If \( \rho^{-1}(\epsilon_1) \geq - C_n M_n \)
both \( g_1(x) \), \( g_2(x) \) are positive for \( x > - \frac{\rho^{-1}(\epsilon_1) + C_n M_n}{2 C_n R_n C'} \)

That means that both \( g_1(x) \), \( g_2(x) \) obtain maximum at either \( x = +\infty \) or \( x = -\infty \) and this value is zero. So this case is trivial.

2. If \( \rho^{-1}(\epsilon_1) < C_n M_n \); \( \rho^{-1}(\epsilon_1) > 0 \)
\( g_1'(x) \) is positive for \( x > - \frac{\rho^{-1}(\epsilon_1) + C_n M_n}{2 C_n R_n C'} \)
and \( g_2'(x) \) is positive for : \( x < - \frac{\rho^{-1}(\epsilon_1) + C_n M_n}{2 C_n R_n C'} \)

That means that \( g_1(x) \) obtains maximum for \( x = +\infty \) and this maximum is zero (trivial), while \( g_2(x) \) obtains maximum for \( x = - \frac{\rho^{-1}(\epsilon_1) + C_n M_n}{2 C_n R_n C'} \)
and this maximum is equal to:

\[
\Phi\left(- \frac{\rho^{-1}(\epsilon_1)}{2 C_n R_n C'}\right) - \Phi\left(- \frac{C_n M_n}{2 C_n R_n C'}\right) 
\]

and (b_{17}) reduces the search for \( - d_{L_0} (f_{1T}, f_{2T}) \) to finding the infimum \( \epsilon_1 \) such that the expression in (b_{17}) does not exceed \( \epsilon_1 \).

3. The case \( C_n M_n < o_j \rho^{-1}(\epsilon_1) \leq - C_n M_n \) is symmetric to ii.
